CLINICAL ASPECTS OF PRIMARY ATYPICAL PNEUMONIA

A STUDY BASED ON 1,862 CASES SEEN AT STATION
HOSPITAL, JEFFERSON BARRACKS, MISSOURI,
FROM JUNE 1, 1942 TO AUG. 10, 1943

MAJOR ARIE C. VAN RAVENSWAAY

AND
LIEUTENANT BERNARD GUMBINER
MEDICAL CORPS, ARMY OF THE UNITED STATES

The increasing incidence of primary atypical pneumonia in certain army hospitals in combination with its frequently prolonged febrile period and slow convalescence is rapidly making it one of the most important causes of man days lost from duty in the military service. The appearance of this disease in significant numbers of cases at the time the medical literature was heralding the conquest of pneumococcal pneumonia is but another indication that medicine will never become a static science.

Recent reports by a commission representing the Surgeon General (Dingle, Abernathy and others¹), Dingle and Finland,² Reimann,³ Seeds and Mazer,⁴ Campbell and his collaborators⁵ and MacLeod⁶ have thoroughly reviewed the present state of knowledge regarding causation, clinical aspects, epidemiology, x-ray appearance and treatment. It has been shown that primary atypical pneumonia, as the name suggests, is a heterogeneous group of diverse causation. Occasional cases and groups of cases have been shown to be caused by influenza A and B viruses associated with staphylococcal and streptococcal infection, psittacosis, ornithosis and related diseases, the virus of lymphocytic choriomeningitis, the Q fever of Australia and American Q fever. In the bulk of the cases studied, however, the etiologic agent has not been determined. It seems probable that the last mentioned group has one etiologic common

denominator and that ultimately it will receive a more definitive name. In the interim it is suggested that cases of atypical pneumonia due to the specific causes listed should be referred to with an appropriate specific name such as atypical pneumonia, cause psittacosis, or psittacotic pneumonia when and as diagnostic methods make this possible. The term primary atypical pneumonia should be reserved for the large group of cases of unknown causation. If the cold agglutinin test or some other comparably simple diagnostic laboratory procedure for primary atypical pneumonia, causation undetermined, is found, the differential study of the entire group of atypical pneumonias will be greatly simplified.

The present study is based on an experience with 1,862 cases of primary atypical pneumonia, causation undetermined, treated at the Station Hospital, Jefferson Barracks, Missouri, from June 1, 1942 to Aug. 10, 1943. During this interval 62 cases of lobar pneumonia of pneumococcus origin also were seen. The differential diagnosis of those two conditions was based on bacteriologic studies of the sputum, the white blood count, the x-ray appearance and the clinical course. Occasional cases occurred in which differentiation was difficult and not clearcut, but it is felt that the foregoing figures give a fair picture of the distribution of cases. The possibility that some of the group classified as primary atypical pneumonia, causation undetermined, in reality were atypical pneumonia of known causation was considered and cannot be denied for the entire group. Two hundred patients gave negative reactions to intradermal tests for coccidiomycosis. Facilities for virus studies were not available at this institution. However, owing to the epidemic character of the disease, the absence of environmental or clinical factors suggestive of the disease processes comprising the group of atypical pneumonia of known causation and the results of virus studies of similar groups of cases at other hospitals,¹ it is felt that the majority of the cases in this series were truly of "causation undetermined" and not just of causation undiscovered.

During the period from June 1, 1942 to Aug. 10, 1943 there were no deaths from primary pneumococcal pneumonia. There were 5 deaths in the group of primary atypical pneumonias. One was due to meningococcal meningitis developing in a patient convalescing from primary atypical pneumonia. In 2 cases at autopsy, consolidation was found, with a gross invasion of hemolytic *Staphylococcus aureus* which had not been observed on sputum cultures. It could not be established whether the bacterial invasion was the primary factor in the disease or occurred secondarily to a primary atypical pneumonia, although the evidence at hand favored the latter explanation. The mortality rate in this series of primary atypical pneumonia including these 3 cases was 0.26 per cent.

PRIMARY ATYPICAL PNEUMONIA: COMMUNICABILITY
AND PRECIPITATING FACTORS

Evidence was obtained which suggests that the susceptibility to primary atypical pneumonia varies greatly.

The majority of the soldiers in this study came to Jefferson Barracks soon after induction into the Army.

Chart 1.—Onset of acute symptoms and admission to hospital after arrival at post.

During the initial period of adjustment with its attendant fatigue and exposure to an unaccustomed environment the incidence was at its peak. After a period of thirty-five to forty days, however, at Jefferson Barracks a soldier's chances of developing the disease dropped to about one sixteenth of what they were on the twenty-fourth day after his arrival (chart 1). This was apparently due to an improvement in the general physical condition or the development of a specific immunity in the group of men involved. It is felt that the latter factor is the more important.

Reimann³ and Dingle and others⁷ have presented evidence indicating that the etiologic agent of primary atypical pneumonia frequently causes upper respiratory tract disease alone and that the majority of such infections occurring in association with epidemics of primary atypical pneumonia are of this type. "Colds" of varying severity occurred with great regularity in new arrivals at Jefferson Barracks during the period of this study, and if the aforementioned theory is correct it would provide an explanation of the indicated immunity.

Since primary atypical pneumonia is an infectious process presumably air borne, and since it was observed that civilian visitors to patients with this disease in the hospital not infrequently contracted it after moderate periods of exposure, it was considered important to determine the degree of isolation desirable for these patients. Attention was specifically directed to the danger of cross infection in wards to which patients with acute upper respiratory infections were sent, with which group approximately one half of the patients ultimately developing atypical pneumonia were admitted before the true character of their disease had become apparent.

Studies were made of the incidence of primary atypical pneumonia in four 55 bed upper respiratory wards during a two months period. In two wards the

patients developing atypical pneumonia were allowed to remain in the wards for treatment and convalescence. In the other two wards the patients were transferred from the wards as soon as the diagnosis became evident. The number of patients present in the wards was essentially the same. In the first group of wards 58 patients developed pneumonia and in the second group this occurred in 64 instances. It should be emphasized that the majority of these cases of pneumonia were developing at the time of hospitalization, that the diagnosis was established within a short time after admission and that only in comparatively few cases did it appear to have been possibly contracted in the wards. Investigation was also made (in view of the incubation period of primary atypical pneumonia) to determine whether any of the patients in these wards not developing pneumonia did so at a later date following this period of hospitalization. It happened that no such incidents were found. It would appear that patients in these wards with upper respiratory disease alone were not endangered by prolonged exposure in the wards to patients with primary atypical pneumonia.

The theory of a common causation of primary atypical pneumonia and associated cases of upper respiratory tract infection is supported by and probably explains this apparent absence of cross infection. It is not suggested that patients with mild primary atypical pneumonia be allowed to remain intermingled with other patients and it is the policy of this hospital at the present time to transfer them to pneumonia wards for isolation in private rooms as soon as the diagnosis is made. However, in case such exposure should inadvertently occur in wards limited to respiratory tract infection the danger to other patients is apparently slight.

EPIDEMIOLOGY

In this series of cases contacts with insect, avian and animal vectors were so infrequent that they were considered of no possible epidemiologic significance. No evidence appeared to contradict the opinion of others that primary atypical pneumonia is air borne.

INCUBATION PERIOD

The incubation period has been estimated to range from two to twenty-one days or longer (Reimann,³ MacLeod⁶). From an epidemiologic standpoint the one common denominator in the cases of this series was their arrival at Jefferson Barracks from many different points throughout the United States, both civilian and military in character. In chart 1 the intervals between arrival at this post and (a) the development of symptoms of pneumonia and (b) the hospitalization of this same group for pneumonia is charted for 203 consecutive patients. It is felt that the rise beginning on the seventh day represents the initial appearance of cases developing from contacts made after arrival at the post (minimum incubation period) and that the maximum summation reached on the fifteenth day indicates roughly the maximum incubation period.

Chart 2.—Maximum temperatures observed in 290 cases.

SYMPTOMATOLOGY AND PHYSICAL FINDINGS

In 297 consecutive cases of primary atypical pneumonia in which the symptoms and physical findings were carefully observed and recorded for statistical purposes the results were quite similar to those reported by previous observers, with the single difference that the disease appeared to be definitely more virulent in this series. This is indicated by the higher maximum temperatures, the greater incidence of chest pain, bloody sputum and complications which these patients developed (chart 2; tables 1 and 2).

Approximately two thirds of this series had a gradual onset with a history of an upper respiratory infection for days or weeks followed by the development of incapacitating malaise, chilliness, fever, cough and chest pain. In one third of the group these symptoms appeared abruptly, requiring early hospitalization. Severe headache was frequently present and at times associated with meningeal signs. Occasionally the possibility of an associated purulent meningitis could be excluded only by spinal puncture.

TABLE 1.—Atypical Pneumonia: Frequency of Occurrence of Symptoms in 297 Cases

	Symptoms	Percentage of Occurrence
Onset	Gradual.....	67.2
	Acute.....	32.8
Constitutional symptoms	Feverishness.....	85.5
	Malaise.....	70.4
	Chilliness.....	63.0

	Thoracic pain.....	69.5
	Substernal.....	20.4
	Pleural on motion.....	47.7
	Thoracic on rest.....	11.2

Physical findings initially were often confusing. Fever was almost invariably present. The most helpful localizing symptom was the presence of rales (56.2 per cent), which varied in character but most typically were dry and crackling and occurred in showers near the end of inspiration. It was observed that they could often be brought out by coughing when not otherwise present. Dulness to percussion was present in 25 per cent of the cases. Dyspnea was detected in 21.7 per cent and diminished breath sounds in 19 per cent. Signs of consolidation or fluid and the presence of a friction rub were noted infrequently.

The initial diagnosis was frequently one of exclusion as x-ray findings and definite localizing physical signs were not present until several days after the onset of the disease. A summary of the symptoms and physical findings is given in tables 1 and 2.

LABORATORY PROCEDURES OF VALUE IN THE MANAGEMENT OF PRIMARY ATYPICAL PNEUMONIA

As Dingle and others¹ have shown, the white blood cell count and differential counts are of little value in uncomplicated primary atypical pneumonia. The experiences in this series of cases was a similar one. The white blood cell count was usually normal and less frequently slightly elevated. No constant help or significant changes were noted in the differential counts.

Sputum examinations and blood cultures were useful when positive in determining primary or secondary pneumonias of bacterial origin.

Valuable information for controlling the management of these cases can be obtained from sedimentation tests done at weekly (or shorter) intervals. In the acute

stage of the disease the sedimentation rate is invariably elevated and ranges from 20 to 40 mm. per hour. As the disease improves this gradually returns to normal, and with recurrences or reactivation it shows secondary rises which can be correlated with clinical and x-ray findings.

By the routine use of this sedimentation test it is possible to follow the progress of atypical pneumonia as satisfactorily as by the routine use of periodic chest plates. This substitution is particularly important because of the present shortage of film and the need for conserving this most valuable material. In the uncomplicated case, films are needed only for diagnostic corroboration, and confirmation of pulmonary clearance before discharge.

Table 3 indicates variations in sedimentation rate correlated with temperature, x-ray and clinical findings in a patient with two recurrences.

THERAPEUTICS DURING THE ACUTE STAGE

Therapy during the acute stage of the disease varied from expectant and symptomatic to the use of the sulfonamides in doses large enough to maintain an

TABLE 3.—Atypical Pneumonia: Case of Recurrence

adequate level. There was no strikingly effective therapeutic agent found.

Because of its apparent success in some of the more toxic febrile cases observed by two of us (G. C. E. and E. P. R.) its possible effectiveness against secondary invaders and its low toxicity, sulfadiazine was used as the therapeutic constant in all cases in which the temperature rose to 102 F. or higher.

Moderate cough and expectoration was considered a helpful physiologic reaction in the bronchitic and atelectatic aspects of the disease. Therefore ammonium chloride was used as an expectorant, and the sedative and narcotic cough medicines were avoided. (It has been shown by one of us⁸ that the use of narcotics in upper respiratory infections is contraindicated. In a series of upper respiratory infections associated with the present epidemic the incidence of pneumonia was significantly increased in cases treated with opiates [powder of ipecac and opium, Dover's powder].) Rest alone has been enough to quiet the unproductive cough in most cases. Codeine and morphine have been used only in cases of severe cyclic cough which disturbed sleep, in gross hemoptysis and in acute pleural pain.

We have frowned on the use of coal tar antipyretics as ineffectual and misleading. The excessive diaphoresis which accompanies their routine use in atypical pneumonia produces a wasteful loss of salts and fluids and sometimes throws the patient into a depressed debilitated condition which we believe counteracts the very symptomatic relief which is desired. Accordingly,

TABLE 4.—A Comparison of Results of Treatment by Prolonged Bed Rest with Treatment of a Conventional Character

Type of Case	Prolonged Bed Rest		Conventional Management

recurrence of pneumonia..	5 † (2.6%)	51.00	41 (23.3%)	51.55
other complications.....	38 ‡ (18.5%)	52.70	38 § (18.5%)	52.00
Total.....	192	33.55	192	41.55

* In 9 cases there was no x-ray evidence of disease. Diagnosis was made on physical findings. These cases not included in computation of average period of x-ray clearance.

† Includes 2 patients who developed effusion during acute stage of disease.

‡ One death and 2 cases of bronchiectasis are not included in computing x-ray clearance time.

§ Three cases of bronchiectasis are not included in computing x-ray clearance time.

acetylsalicylic acid is reserved for symptomatic relief when indicated rather than as a routine measure.

The usual therapeutic indications in pneumonia have governed our use of oxygen, intravenous fluids and blood plasma.

THE MANAGEMENT OF THE ACTIVE (POST-FEBRILE) PERIOD

A very important factor contributing to the long period necessary for recovery of the patients with atypical pneumonia seen at Jefferson Barracks was the frequent recurrences which developed under conventional treatment. A recurrence was arbitrarily defined as a febrile rise of 100 F. or more appearing after ninety-six hours of normal temperature with clinical or x-ray signs of an extension or reactivation of the pulmonary process. Studies were made to determine the optimum method of postfebrile care for the prevention of these complications (other phases of this study are still in progress).

Because of the relatively chronic nature of the pulmonary process in atypical pneumonia and the proved value of rest in pulmonary tuberculosis, it was decided

to determine whether these patients would benefit by a prolongation of the usual postfebrile period of bed rest.

For the purpose of study, our controlled cases were divided into four arbitrary stages: acute (until free from fever for four days), active (until fever free for fourteen days), subsiding (after fourteen afebrile days and until physical examination, x-ray and sedimentation rate were normal) and convalescent (from subsiding stage to full duty).

The following physical arrangements were made: All patients developing pneumonia were transferred to "acute pneumonia wards." On admission to these wards patients were alternately labeled as "ambulatory" or "bed rest" and they retained this designation during their period of hospitalization. The entire group was kept at complete bed rest until they had been free from fever for four days. Then those designated as "ambulatory" and "bed rest" were separated, and each group was sent to a different ward for controlled study. At this point the occasional patients who had been found to have pneumococcic pneumonia were dropped from the series.

The ambulatory group (who had had four afebrile days of bed rest before transfer) were then permitted to get up when and as they felt like doing so, there being no compulsion to do more than appealed to them. In the event of a recurrence or reactivation of the pulmonary process they were returned to the acute pneumonia wards and passed through the cycle of acute treatment again.

The group sent to the "bed rest" ward were kept in bed for an additional ten days (total fourteen days). This period of time was selected arbitrarily. Following this they were permitted to get up when and as they felt like doing so.

After both groups were ambulatory they were transferred to the "subsiding" wards for further care.

The results in this controlled study of 384 cases is summarized in table 4. In the group treated by prolonged bed rest the percentage of recurrence was 2.6 and in the group treated by a conventional type of care the percentage of recurrence was 23.3.

In spite of the delay in becoming ambulatory, the decrease in recurrences reduced the average period of hospitalization in the "bed rest" group to 33.55 days as compared to 41.55 days in the "ambulatory" group.

This procedure was set up for statistical purposes and obviously did not necessarily represent the ideal method of managing the individual patient, as it does not give consideration to variations in the virulence of the disease or the resistance of the individual patient. After the completion of this statistical study we adopted the policy of keeping all patients with active atypical pneumonia at bed rest and isolated until their sedimentation rate has decreased to 10 mm. or less in one half hour.

TREATMENT DURING THE SUBSIDING AND CONVALESCENT STAGES (USE OF CONVALESCENT TRAINING PROGRAM⁹)

Since rest seemed to be so important during the "active" stage of the disease, at the beginning of this study the tendency was to limit activity during the "subsiding stage" as well. Physical rehabilitation was not begun until the pneumonia was entirely resolved. A graduated program of convalescent physical training

8. Rusk, Howard A., and van Ravenswaay, Arie C.: Sulfadiazine in Respiratory Tract Infections: Its Value in Treatment During Winter 1942-1943 at Jefferson Barracks, Missouri, J. A. M. A. 122:495-496 (June 19) 1943.

9. This program is an integral part of the Convalescent Training Program now operating in all Army Air Force hospitals and is administered by a trained group of officers and enlisted men under close medical supervision.

was established in the country (Camp Babler) to which patients were sent after discharge from the Station Hospital. This worked out very well, and patients were returned to duty in much better condition than before this program was instituted. However, by experimentation and observation it was found that it was unnecessary to wait until x-ray and physical findings had completely cleared before beginning physical reconditioning and that patients who had been afebrile for fourteen days could tolerate exercise without reactivation and that clearing by x-ray proceeded as rapidly as it did in those on the less vigorous program.

Ultimately it appeared, as previously stated, that a thirty minute sedimentation reading of 10 mm. or below was a more satisfactory criterion for determining the beginning of the "subsiding" stage than the arbitrary period of fourteen afebrile days. The patient now begins the physical portion of his convalescent training program at this point. The rapidity of his progress on the road to physical rehabilitation is regulated by his exercise tolerance.

At present a twelve day physical reconditioning program in the hospital is used during the "subsiding" phase of the disease. In this the first five days are a preconvalescent or test period. If the exercise tolerance is good and the sedimentation rate continues to drop during this test period, the patient continues with increasing stages of physical activity to approximate general military duty by the twelfth day of the program. When the sedimentation rate at sixty minutes is 10 mm. or below and exercise tolerance is excellent, the final x-ray film is taken before discharge to duty. Organized lectures, demonstrations, movies and entertainment are a part of the convalescent program. Thus, manpower hours of useful training are salvaged and morale is maintained. The patients are enthusiastic, ward morale is high, manpower conservation gratifying. The individual convalescent is observed and regulated by his ward officer during the program, and his exercise tolerance evaluated before general duties are assumed.

By means of the sedimentation rate we have been able to anticipate x-ray clearance and exercise tolerance so that clear chest plates, normal sedimentation and full duty exercise tolerance all obtain at nearly the same time. This has saved two or three weeks of noneffective days per patient.

The study has given us some insight into the behavior of the infectious process in the various stages. The "acute" stage appears to be the most infectious; the "active" stage is still infectious and is accompanied by lowered resistance, as is shown by reactivation with exercise and cross infection. The "subsiding" stage is apparently noninfectious, resistance is raised against cross infection; graduated exercise is well tolerated so that full activity may be achieved by the time the x-ray film is clear, when a proper program is provided and the patient carefully followed.

COMPLICATIONS

That the atypical pneumonia of Jefferson Barracks of 1942-1943 has been more virulent than most reported series is borne out by the greater number of acute and seriously ill patients, increased x-ray clearance time (table 5), increased frequency of bloody sputum, cyanosis and chest pain, as well as complications. Of 493 consecutive patients admitted after March 10, 1943 (378 of whom had been discharged by August 10) the most frequent complication was the development of pleural fluid. There were 48 (9.7 per cent) cases

corroborated by x-ray examination; of those 13 (2.6 per cent) showed massive effusions requiring thoracentesis and of the latter number 7 (1.4 per cent) in which empyema developed requiring surgery (rib resection). The importance of these pleural complications can be measured in hospital days. While thirty-two days was the average time for chest clearance by x-ray examination in the uncomplicated cases, pleural effusion, even minimal, raised the figure to forty-six days. Empyema with its incident operations and slow healing raised the figure to two and one-half to four months, not counting the necessary prolonged convalescent period before active duty. Recurrence and reactivation carried with them an average x-ray clearance time of fifty-two days. These complications occurred in 23 per cent of these patients who were permitted to become ambulatory after being afebrile for four days and in only 2.6 per cent of those treated with prolonged bed rest. The inevitable conclusion is that atypical pneumonia patients should be treated in bed until the sedimentation rate shows quiescence.

Residual localized chronic bronchitis and bronchiectasis were serious complications which occasionally

† In this instance 98 days represents the average period of hospitalization before discharge with x-ray diagnosis of bronchiectasis.

occurred. There were 3 cases of the former and 11 of the latter. Both were characterized by persistence of cough and expectoration, especially in the morning, and poor exercise tolerance. Physically and roentgenologically the two conditions are indistinguishable. The bronchogram alone can differentiate them. Physical findings invariably showed a definitely localized area of moist and bronchial rales, with or without dullness. X-ray films either were normal or showed increased bronchial markings in the area or a persistent shadow, interpreted as unresolved pneumonia. These complicating processes did not prevent the characteristic return to normal of the sedimentation rate coincident with the resolution of the initial pneumonic process. The bronchogram revealed the local damage in the cases of bronchiectasis and showed a relatively normal bronchial tree with more or less peribronchial infiltration in the cases of chronic residual bronchitis. Whether the latter group will ultimately develop bronchiectasis cannot be predicted. We recognize these cases as troublesome, manpower wasting and relatively intractable to therapy. Seven of the 11 patients in the bronchiectasis group gave a history of intermittent or continual chronic dry or productive cough extending over months to years.

which was compatible with preexisting bronchiectasis. The remainder had no past history suggestive of chronic pulmonary pathologic changes. In the absence of a suitable x-ray examination before the onset of the atypical pneumonia it is impossible to determine accurately how many of this group had preexisting bronchial damage. It seems probable that at least 4 developed bronchiectasis during their hospitalization. Certainly all are incapacitated now by poor exercise tolerance, when previously they could exercise vigorously without symptoms.

In this series 2 cases of thin walled abscesses developed. Acid fast and coccidiomycotic factors were ruled out. The patients are still under observation and appear to be making spontaneous recovery, although full x-ray clearance has not been obtained. There was 1 patient with unexplained massive and continued hemoptysis requiring three blood transfusions. This patient has now returned to full duty with complete healing.

In the controlled group 2 cases of nonspecific urethritis (presumed to be viral in etiology since no bacterial cause could be found) and 1 case of Stephens-Johnson syndrome (conjunctivitis, and stomatitis associated with atypical virus pneumonia) represented the only extrapulmonic complications of our series.

There were 2 patients with acute abdominal localization of pain who were conservatively followed by the surgical department. Atypical pneumonia apparently accounted for all their symptoms.

INTERCURRENT INFECTIONS

The study of intercurrent infections in our controlled series has revealed some interesting figures, which may point the way to rational therapy for atypical pneumonia. These figures do not lend themselves to absolute statistical evaluation in all cases but suggest a trend which we believe is possibly significant. Remembering that the x-ray clearance time of uncomplicated cases was approximately thirty-two days, the presence of measles, red or German, raised that time to from forty-three to seventy-three days (average fifty-five days for 12 patients). Syphilis, another depressor of resistance and white blood cell count, was accompanied by very slow clearing, as would be expected. However, streptococcal diseases, scarlet fever and streptococcal pharyngitis had a much shorter period of clearance, varying from ten to fourteen days (average thirteen days for 6 patients). Cases accompanied by acute otitis media showed an x-ray clearance period of six to twenty days (average sixteen days for 4 patients). We have noticed in our series of cases of primary atypical pneumonias that those patients with higher degrees of fever and higher white blood cell count cleared more quickly and that a rising white blood cell count was a good prognostic sign. Will raising fever or maintaining it and stimulating polymorphonuclear response constitute a helpful alternative effect? We are about to investigate these possibilities.

CONCLUSIONS

1. The primary atypical pneumonia, causation undetermined, seen in 1,862 cases at Jefferson Barracks during the period from June 1, 1943 to Aug. 10, 1943 was more virulent than in other reported series.

2. For optimum results the clinical management of primary atypical pneumonia of the type seen at Jefferson Barracks during the past year should include a more prolonged period of postfebrile bed rest than ordinarily is indicated in pneumococcal pneumonia of similar age groups.

3. The determination of the sedimentation rate is a useful laboratory procedure for following the course of this disease.

4. The judicious use of a physical reconditioning program during the subsiding and convalescent phases of primary atypical pneumonia is an important adjunct in shortening hospitalization and reducing the incidence of recurrence.

THERAPEUTIC CURE OF ACUTE EXPERIMENTAL TOXOPLASMOSIS IN ANIMALS

DAVID WEINMAN, M.D.

AND

ROBERT BERNE, M.D.

BOSTON

The disease toxoplasmosis is almost invariably fatal in man. Therapy has been unsuccessful; in the few recoveries which have occurred there is no convincing evidence that this outcome was appreciably influenced by the nonspecific medication employed. A principal cause for failure of therapy may well have been the short period in which the patients were available for treatment, since death has often followed the appearance of the initial symptoms within a few days. Practically, therefore, decidedly beneficial results in man may be expected only from those drugs which in animals have experimentally been proved effective when administered during the acute disease and shortly before death.

In this report it will be shown that appropriate sulfonamides will cure a high percentage of otherwise fatally infected animals even when treatment is instituted a few days before the date of expected death. It is felt that these results warrant thorough trial of the same treatment in human cases.

The first record, to our knowledge, that the sulfonamides were at all effective in vivo is that of Sabin and Warren.¹ These authors experimented with mice, adding different sulfonamides to the diet. They observed a notable prophylactic effect but were unable to effect cures if administration of the drug was delayed beyond the second day after infection. Carried over to man, this would signify probable ineffectiveness once symptoms were present. Five rabbits were treated as late as the third day after infection; 3 which received drug in the diet died, while 2 injected intraperitoneally survived. Study of the data of these authors suggested that blood levels adequate for maximum benefit may not have been obtained, so that the method of administration rather than ineffectiveness of the drug was primarily responsible for the unsatisfactory results. The present study was undertaken to test this very point.

METHODS AND MATERIALS

In order to reproduce the conditions in which human patients become available for treatment, therapy was initiated late in the course of the infection. The period of expected survival was determined and the initial dose given to some animals at the expiration of the first third of this period, to others at the end of the second third, and others received it at various later intervals.

From the Department of Comparative Pathology and Tropical Medicine, Harvard Schools of Medicine and Public Health.

1. Sabin, A. B., and Warren, Joel: Therapeutic Effect of the Sulfonamides on Infection by an Intracellular Protozoan (*Toxoplasma*), *J. Bact.* **41**: 80 (Jan.) 1941; Therapeutic Effectiveness of Certain Sulfonamides on Infection by an Intracellular Protozoan (*Toxoplasma*), *Proc. Soc. Exper. Biol. & Med.* **51**: 19-23 (Oct.) 1942.

Sulfapyridine, sulfathiazole and sulfadiazine were suspended in cottonseed oil and injected subcutaneously; the more soluble sodium salts, after dissolution in saline solution, were injected intraperitoneally. Administration was either twice daily at twelve hour intervals or in some instances three times a day spaced eight hours apart. Blood levels of the drugs were determined by the methods described by Bratton and Marshall.²

The toxoplasma strain, originally isolated from guinea pigs, is regularly fatal to mice following intraperitoneal injection of adequate doses. This route was used for all the mice reported. In the case of this organism it is impossible to state in a very exact way

RESULTS

With the first series of infected animals, treatment was delayed until the fifth day after infection. Untreated controls died in an average of fifteen days. In other words, treatment was begun at the expiration of one-third the period of expected survival.

The results with sulfapyridine were strikingly successful. Of 17 mice treated with sulfapyridine in oil or with sodium sulfapyridine, 16 survived throughout the observation period, which was set at twenty-eight days, being a convenient period nearly double that in which the average control death occurred. This represents a therapeutic cure rate of 95 per cent. Of the 6 untreated controls, 1 unexpectedly recovered and

TABLE 1.—First Series

Drug	Number of Mice	Day Treatment Began *	Daily Dose per Mouse	Period of Therapy	Blood Levels			Survivors Observation Period (28 Days)
					Day of Treatment	Hours After Infection	Mg. Drug 100 Cc. Blood	
Sodium sulfapyridine	6 (4350)	5	2 × 0.010 Gm. for one day = 0.02/day 3 × 0.010 Gm. for two days = 0.03/day 2 × 0.010 Gm. for three days = 0.02/day	Six days	6
	5 (4349)	5	2 × 0.010 Gm. for one day = 0.02/day 3 × 0.010 Gm. for two days = 0.03/day 2 × 0.010 Gm. for six days = 0.02/day	Nine days	2	6½	15.0	4
				Nine days	5	3	25.0

TABLE 2.—Second Series

Drug	Day of First Dose *	Number of Mice	Daily Dose	Period of Administration	Outcome
Sulfapyridine in oil	10	2	0.015 Gm. × 2 at 12-hour intervals = 0.03/day	9 days	1 survived 85 days
	12	1	0.015 Gm. × 2 at 12-hour intervals = 0.03/day	3 days	Dead 13th day (treatment ineffective)
	13	2	0.015 Gm. × 2 at 12-hour intervals = 0.03/day	7 days	Dead 20th day (treatment ineffective)
	14	1	0.015 Gm. × 2 at 12-hour intervals = 0.03/day	5 days	2 survived 85 days
Sulfathiazole in oil	10	2	0.02 Gm. × 2 at 12-hour intervals = 0.04/day	5 days	Dead 17th day (treatment ineffective)
	12	1	0.02 Gm. × 2 at 12-hour intervals = 0.04/day	2 days	All died as if untreated within 24-48 hours after first dose †
	13	1	0.02 Gm. × 2 at 12-hour intervals = 0.04/day	1 day	
	14	2	0.02 Gm. × 2 at 12-hour intervals = 0.04/day	1 day	
None (control group)	..	5	0	No recoveries; average death 16 days

* Counted from and including the day of infection.

† Sulfathiazole blood levels (uninfected mice) 7 hours after last injection 7.95 to 9.45 mg. per hundred cubic centimeters of blood; 12 hours after, 10.3 to 10.5 mg. per hundred cubic centimeters.

the injected doses, since the infective agents are not distributed uniformly in an inoculum or freed from the tissue in which they occur. Nonetheless an approximation was obtained for the mice reported in series 1 by the progressive dilution method, an inoculum of 0.5 cc., as in the therapy experiments, but diluted 1:20,000 still proving fatal. The average survival period of the dying untreated controls in series 1 was fifteen days. In series 2 the dilution method was not employed; since, however, untreated controls died in sixteen days, the infective dose was probably of the same magnitude in the two series.

At the conclusion of the experiment survivors were tested for chronic infection by direct examination of the brain. This, if negative, was complemented by inoculation of mice with other portions of the same brain.

the others died, the spontaneous recovery rate being 17 per cent. Details of treatment are given in table 1.

These results were so promising that we were led to see how late in the infection therapy might still be effectively instituted. In this second series the 5 controls died in an average period of sixteen days. The treated mice received sulfapyridine in oil ten, twelve, thirteen or fourteen days after infection. Of the 6 treated mice in this set half died in the same period as the controls, but 50 per cent survived during an observation period prolonged in this instance to eighty-five days. Of these mice, 2 received the first treatment as late as the thirteenth day after infection, that is, three days before their anticipated death; both recovered, as may be seen in table 2.

In all these experiments the period of administration of the drug varied from six to nine days. There is no indication that the longer period was advantageous therapeutically, and, since the drugs are toxic, the shorter period is to be preferred.

2. Bratton, A. C., and Marshall, E. C., Jr.: A New Coupling Component for Sulfanilamide Determination, *J. Biol. Chem.* **128**: 537-550 (May) 1939

Blood levels with sodium sulfapyridine varied between 10.5 and 25.0 mg. in 100 cc. of blood. In terms of milligrams per hundred cubic centimeters, at different intervals after injection, the blood levels on the twice daily schedule were at 3 hours 25.0, at 6½ hours 15.0, at 7½ hours 11.0 and at 12 hours approximately 10.5. With sulfapyridine in oil given at noon and midnight, the blood levels did not rise as high or drop as low as with the sodium salt. Three hours after injection the blood level varied between 7.0 and 15.6 mg. per hundred cubic centimeters, at 5½ hours it was 15.0 and at 11 hours 12.2.

Trials with other sulfonamides were not sufficiently extensive to permit of any final conclusion. With sodium sulfadiazine we were able to cure nearly all mice of a small batch when treatment was commenced the fifth day. It is of particular interest that this result was obtained after only three days of treatment, the mice receiving 0.02 Gm. the fifth day in two equal doses twelve hours apart, 0.03 Gm. on the sixth in three equal doses at intervals of eight hours, and a single dose of 0.01 Gm. on the seventh day. While these results are encouraging, the amounts injected, although reported to be safe, were found to be dangerously near the toxic dose, blood levels rising to above 20 mg. per hundred cubic centimeters three hours after injection. It is possible that smaller safer doses might prove effective. Sulfathiazole in oil started on the tenth, twelfth, thirteenth or fourteenth days after infection cured no mice; the blood levels obtained, 8.75 mg. per hundred cubic centimeters at 7 hours and 10.4 at 12 hours, were perhaps too low for maximum benefit. As already noted, mice treated with fapyridine ten to fourteen days after infection were ed in about half the cases; however, the blood ncentrations attained varied between 7.0 and 15.6 mg. per hundred cubic centimeters.

CHRONIC INFECTION OF CURED MICE

Recently one of us has shown³ that mice receiving very small doses of virulent toxoplasmas will recover but remain carriers, the infection persisting as an inapparent one for long periods of time. When the carriers died or were killed and the viscera examined, the brain in every instance was found to be heavily infected with living virulent organisms. Other data were presented which indicate that the carrier state may exist in man.

The question naturally arose whether in the present experiments the sulfonamides in effecting a cure of the disease eradicated the infection or only aided in producing the carrier state. The evidence is unequivocal; we have no proved case of sterilization of the infection, for in every instance tested the cured mice were found to be carriers. The toxoplasmas were present in the brain, being usually quite numerous and shown in every test to be virulent by passage to new mice.

This result was obtained whatever the drugs used: sulfapyridine, sodium sulfapyridine, sodium sulfadiazine and sulfathiazole. It also seemed to be independent of the length of the period of administration as well as of the dose of drug and was found to occur even in experiments (not otherwise reported in this paper) in which the drug was given prophylactically before infecting the animals. It seems justified to conclude, therefore, that the sulfonamides cannot be relied on to eradicate the carrier state.

CONCLUSIONS

1. Sulfapyridine is strikingly successful in curing acute toxoplasmosis in mice.
2. The recovery rate is the higher the earlier in the course of the disease treatment is started. When treatment is initiated at the expiration of one-third the period of expected survival, nearly all animals recover. If treatment is delayed beyond the end of the second third of this period, only half the animals survive. However, some animals are cured by sulfapyridine administered as late as three days before expected death.
3. Therapy cures the disease but it does not sterilize the infection. The cured mice remain carriers and retain virulent organisms in the brain.
4. The results appear to warrant use of the sulfonamides in treating human acute toxoplasmosis.

SULFADIAZINE IN THE TREATMENT OF THE COMMON COLD

RUSSELL L. CECIL, M.D.

NEW YORK

MAJOR NORMAN PLUMMER

MEDICAL CORPS, ARMY OF THE UNITED STATES

AND

WILSON G. SMILLIE, M.D.

NEW YORK

The common cold derives its medical importance chiefly from the fact that it is followed so frequently by secondary infection. The uncomplicated cold, now generally accepted as caused by a filtrable virus, runs a mild course, usually afebrile, and clears up completely in four to seven days. On the other hand, a cold complicated by a secondary bacterial infection which may involve the sinuses, middle ear, mastoids, larynx or lungs can lead to a fatal outcome. It is evident, therefore, that the cold problem would be greatly simplified if all colds could be retained in the uncomplicated form by some relatively harmless medication. The value that sulfadiazine, the least toxic of the sulfonamides, might have in this role is the consideration of this study.

It is generally agreed that the sulfonamides have little or no effect on the virus initiating the common cold, but it has been accepted that they are effective agents against the pneumococcus and the hemolytic streptococcus. Also there is evidence that they are effective, but to a lower degree, against *Haemophilus influenzae* and the hemolytic staphylococcus, the other two most common secondary invaders of the respiratory tract following colds.

The literature on the use of the sulfonamides in acute coryza per se is comparatively meager, although its use in localized disease of the respiratory tract following colds is quite extensive. But even in such common conditions as tonsillitis and sinusitis there is no unanimity of opinion regarding the indications and value of the sulfonamides. In 1937 Long and Bliss¹ reported favorably on the use of sulfanilamide by mouth in acute pharyngitis and tonsillitis. On the other hand,

From the Medical Service of the New York Hospital and the Departments of Medicine and Public Health and Preventive Medicine of Cornell University Medical College.

3. Weinman, David: Chronic Toxoplasmosis, *J. Infect. Dis.* **73**: 85-92 (July-Aug.) 1943.

Rhoads and Afremow² in a controlled series of cases of pharyngitis and tonsillitis found that sulfanilamide did not lessen the severity of symptoms, reduce the incidence of complications or shorten the duration of the carrier state. Kernan³ found that sulfanilamide orally did not alter the ordinary course of tonsillitis but that complications were fewer when it was used. This opinion is the one most commonly accepted today, even though there have been improvements in sulfonamide therapy through the introduction of drugs more effective and less toxic than sulfanilamide.

In sinusitis there is particularly great divergence of opinion on the value of the sulfonamides. Turnbull⁴ reported that a large proportion of patients with chronic sinusitis were benefited by spraying the nasal cavities with a 5 per cent solution of sodium sulfathiazole. No untoward effects were observed in Turnbull's series of 47 cases. This enthusiasm for the local use of the sulfonamides in chronic sinus infection has not been borne out by later reports, and there have been studies indicating that a 5 per cent sodium sulfathiazole solution is deleterious to the mucous membranes. Gundrum⁵ tested the effect of sulfonamide preparations on the nasal mucous membrane of rabbits and found that sodium sulfathiazole in 4.7 per cent solution was locally destructive following nasal instillation. Sodium sulfadiazine, while not so frankly destructive, was also injurious. Otolaryngologists are in greater accord on the value of the sulfonamides in acute sinusitis and in acute otitis media. Bowers⁶ believes that they exert their effect most strikingly in fulminating sinus infections and that in acute otitis media, if oral chemotherapy is instituted early, the duration of discharge and the number of mastoidectomies are both reduced by 50 per cent. For local use Bowers⁶ prefers sulfadiazine or sulfathiazole powder applied directly to the mucous membranes. Silcox and Schenk⁷ have used a 5 per cent suspension of microcrystalline sulfathiazole for the treatment of acute and chronic sinusitis, the suspension being instilled directly into the sinuses. In addition to the differences of opinion over the relative value and safety of the different sulfonamides in their crystalline and liquid forms, the relative value and safety of oral and local administration remains highly controversial.

The value of the routine use of the sulfonamides in the treatment of the common cold has been widely speculated on in medical circles, but very little detailed investigation has been carried out on this problem. Bordley, Crowe, Dolowitz and Pickrell⁸ at Johns Hopkins Hospital treated a small alternate group of nurses coming down with colds by spraying the pharynx and nasal passages with a 2.5 per cent sulfadiazine in 8 per cent triethanolamine solution. In addition to definite symptomatic relief they observed a reduction in complications and a decrease in the secondary bacterial

invaders in the nasopharynx, particularly the hemolytic streptococcus. While this study is very suggestive, it is not convincing because of the small number of cases included. Furthermore, the method of treatment reported is not entirely practical because in order to obtain results it is necessary to spray the pharynx eight times daily for the first two days and then five or six times for three days.

Rusk and van Ravenswaay⁹ have recently published their results on the oral use of sulfadiazine in the treatment of acute febrile respiratory infections which were seen in a large army station hospital during the winter of 1942-1943. Doses of drug (3.0 Gm. initially followed by 1.0 Gm. every four hours) similar to those used in pneumonia were administered until improvement occurred. In the 317 treated patients compared with 314 comparable controls the authors observed no significant difference in either the length of the febrile period or in the period of hospitalization. Contrariwise, Siegel¹⁰ observed decided differences with and without sulfadiazine in alternate groups of feeble-minded children with acute febrile respiratory infections, to which such individuals are particularly susceptible. In this reported series the incidence of serious secondary infections and the duration of the febrile period were considerably lessened.

This brief summary of the literature indicates that the exact role of the sulfonamides in the treatment of upper respiratory infections has not been accurately determined. Our purpose in this study has been (1) to determine the effects of small oral doses of sulfadiazine on the nasopharyngeal flora of persons suffering from acute coryza and (2) to ascertain, if possible, the indications for the use of sulfonamide therapy in upper respiratory tract infection, estimating the benefits to be expected in such cases from this therapy.

METHOD

The subjects were volunteers from the personnel of the New York Hospital.¹¹ They attended a "cold clinic" where they could be studied and treated systematically. To the majority of them colds had become a serious problem because of their frequency and severity.

At the beginning of observation a detailed respiratory history was taken and a careful examination¹² of the upper respiratory tract was made. At the start of therapy and every second or third day during the follow-up, the following procedures were carried out:

1. Oral temperature.
2. Complete blood count on all those actually receiving sulfadiazine, and hemoglobin determination on the others.
3. Record of symptoms with their intensity at time of visit
4. Examination of the upper respiratory tract.
5. Nasopharyngeal culture.

In addition, gross and microscopic urine examinations were made at the start, and later examinations were made if there was indication for them. Also the levels of sulfadiazine in the blood were determined twice during the course of therapy by a micromodification of the

Bratton and Marshall method.¹³ This procedure served as an excellent check as to whether the subject was taking the drug as directed.

The treatment as far as the patients knew was the same in all cases. In addition to written directions for the usual symptomatic and hygienic measures they all received an envelop containing 24 tablets with instructions to take 2 immediately and then 2 three times daily (on rising, at midday and at bedtime) until the medicine was gone. At the start of the study all of the subjects

Nasopharyngeal cultures were taken at the time therapy was initiated and at frequent intervals (usually every second day) thereafter in order to determine the changes that occurred in the nasopharyngeal flora following the therapy.

CULTURE TECHNIC

A small cotton swab on a curved malleable aluminum wire was inserted into the posterior nasopharynx. West tubes were not used, as it is possible with skill to avoid contamination of the swab with the saliva. The swab was put in a tube of 3 cc. of hormone blood broth. With as little delay as possible a measured amount of this infected broth was spread directly on blood hormone agar plates. The blood broth after incubation for four hours, was also injected intraperitoneally into white mice as a further check on prevalence of the pneumococcus types and other pathogens. The blood agar plates were incubated for forty-eight hours and read. An attempt was made to estimate the number as well as the type of the various pathogenic agents that were encountered. For example, if *Haemophilus influenzae* (Pfeiffer's bacillus) was encountered the approximate number and relative proportion of these organisms on the plate were determined. The total count and the prevalence of individual pathogens were compared with the findings in each subsequent culture. Serial cultures made it possible to determine any change in either quantity or quality of the organisms found in the nasopharyngeal cultures.

INITIAL CONTROL STUDY

Before initiating the therapy of persons with colds, we gave the drug to a group of 6 normal subjects. Nasopharyngeal cultures were obtained daily to determine the effect of sulfadiazine on normal nasopharyngeal flora. This work was done in August, when pathogens such as pneumococci and beta hemolytic streptococci are normally at a low level in the throat. The striking features of this initial study were:

1. The uniformity of character and relative distribution of various nasopharyngeal organisms in the throat of any given individual.
2. The pronounced reduction of normal nasopharyngeal flora that followed administration of sulfadiazine. When the blood level reached a concentration of 4 to 6 mg. per hundred cubic centimeters the effect of the drug was clearcut.
3. The rapid return of flora to former prevalence and relative distribution within two or three days after the drug was discontinued.

The results of a typical experiment are summarized in figures 1 and 2. In the first illustration photomicrographs of daily blood agar plates from 1 subject show the decrease in the normal nasopharyngeal flora following the administration of sulfadiazine 1 Gm. three times daily for four days. Figure 2 shows the total colony count and correlates it with the dosage and blood levels of sulfadiazine. These illustrations show a striking change during the period of treatment but rapid return of the organisms to their normal pattern after the cessation of drug treatment.

ALTERNATE CASE STUDY

Seventy-two separate colds in 66 persons were treated in the "cold clinic" and carried through a complete series of bacteriologic and clinical observations. In the 72 cases the 3.0 Gm. daily dosage of sulfadiazine was administered to 48 subjects and acceptable blood

Fig. 1.—Decrease in normal nasopharyngeal flora following oral administration of sulfadiazine 3 Gm. daily for four days.

received sulfadiazine, which meant that they received 1.0 Gm. three times daily for four days, or a total amount of 12 Gm. During the latter part of the study alternate patients received a placebo tablet which could not be distinguished from the drug. The treatment usually was commenced on about the second or third day of the cold when symptoms were established, but a few late cases also were included. The period of time covered by this study extended from October 1941 to June 1942.

13. Bratton, A. C., and Marshall, E. K., Jr.: A New Coupling Component for Sulfanilamide Determination, *J. Biol. Chem.* 128: 537 (May) 1939.

sulfonamide readings were made. Nineteen received the control tablets and 5 were given sulfadiazine tablets but the blood level determinations indicated either that the drug was not taken or that it was not absorbed. Therefore, at the start, the cases can be divided into

Fig. 2.—Effect of 12 Gm. of sulfadiazine on normal nasopharyngeal flora.

two groups; 48 in which sulfadiazine was administered and 24 in which specific therapy was not administered.

Before analyzing the results in the cases in which sulfadiazine was administered it seemed wise to create a base line for comparison by studying the control series. This group included 24 patients: 19 assigned originally to the control group and 5 from the treated series who, it was evident, did not take or absorb the drug. The bacteriologic findings from the nasopharyngeal cultures in these cases followed a pattern already described by Smillie.¹⁴ Early in the cold and during the stage of the watery secretion from the upper respiratory tract the total bacterial count was reduced. However, after this the total count increased, frequently with a definite predominance of one or more of the pathogens such as the pneumococcus, beta hemolytic streptococcus or *Haemophilus influenzae*. Of the 24 cases, 4 showed a combination of pneumococcus (types 3, 8, 20 and 21) and *H. influenzae*, which during the height of the infection appeared on the plates in large numbers. In 8 cases the pneumococcus (types 6, 8, 11, 20 and 31) was isolated in the first examination. The pneumococcus grew out in increased numbers in all instances but 1, in which it disappeared. *Haemophilus influenzae* was present alone four times and in 2 cases showed increasing numbers on the subsequent cultures. The remaining 8 control cases showed only the usual throat organisms, but in all of these the growth increased during the period of the infection, after the transient decrease.

14. Burky, E. L., and Smillie, W. G.: Nasopharyngeal Flora in Health and During Respiratory Disease in Isolated Communities in Alabama and Labrador, *J. Exper. Med.* 50: 643 (Nov.) 1929.

Clinically these 24 patients showed an ordinary run of colds. Several lost time from work, 1 because of a secondary tonsillitis and another because of severe bronchitis and sinusitis with fever. Six developed a moderate but short lasting sinusitis and 2 had a moderate bronchitis. The colds of 11 patients were uncomplicated except that 3 had prolonged sore throats. Three gave such vague descriptions of their symptoms that they could not be used in appraisal of the clinical findings.

A diagrammatic representation of the course of symptoms and changing nasopharyngeal flora in a control case is shown in figure 3. A key to symbols for symptoms and organisms adjoins this graph. In following symptoms, particular attention was given to malaise, sore throat, rhinorrhea, sinus congestion, hoarseness and cough, and each of these symptoms when present was graded as to whether it was slight, moderate or severe. The organisms that were most carefully identified and included in the graphs are pneumococcus, beta hemolytic streptococcus, *H. influenzae* and hemolytic *Staphylococcus aureus*. *Staphylococcus albus*, alpha and gamma streptococci and diphtheroids were almost universally present in the nasopharynx.

Figure 3 (M. H.) shows the onset with slight malaise, sore throat, rhinorrhea, hoarseness and cough. On the second day the sore throat and rhinorrhea became moderately severe, and on the fifth day the malaise also increased. These symptoms continued through the seventh day but had disappeared by the tenth day except for a slight rhinorrhea. The first culture was not made until the fifth day; consequently the initial decrease in organisms does not show. This culture showed a heavy growth of *Staphylococcus albus* and other mouth organisms and a few colonies of hemolytic *Staphylococcus aureus* and *Haemophilus influenzae*. On the seventh day, when the cold was still active, the

Fig. 3 (M. H.).—Control patient treated with milk sugar tablets. No change in pharyngeal flora; symptoms followed usual course.

culture continued to show a heavy growth with an increase in the number of colonies of *Staphylococcus aureus* and *H. influenzae*. On the tenth day, when the symptoms had subsided, the total number of organisms as well as the number of pathogens in the nasopharynx were decreasing.

TREATMENT WITH SULFADIAZINE

In the cases treated with sulfadiazine the most striking effect was the uniform reduction in the number and variety of organisms in the nasopharynx as measured by the serial nasopharyngeal cultures. Thirty-eight of the 48 cases studied showed a moderate or pronounced reduction in the total colony count. In some of these the effect was striking, showing on the plates a change from a heavy growth to a few scattered colonies. The total number of pathogens was also consistently reduced, but this seemed generally to be in proportion to the total reduction of organisms. Usually the pneumococcus, beta hemolytic streptococcus or other pathogen would not entirely disappear but would continue to show a few colonies and then return in larger numbers when the sulfadiazine was discontinued. The rapid return was pronounced in 6 of the 48 cases. In 10 instances no reduction in organisms was measured, but 5 of these showed a scant growth and no pathogens at the start, and the flora was held in check at that level.

The prevailing significant secondary organisms encountered in these cases were the pneumococcus in 20 patients, *Haemophilus influenzae* in 13, beta hemolytic streptococcus in 7 and hemolytic *Staphylococcus aureus* in 4. Nine persons in this entire group harbored no recognizable pathogens. In a number of instances more than one of these organisms were isolated. The pneumococcus types encountered were type 3 four times, type 6 three times, type 8 twice, type 18 three times, type 15 twice and types 4, 7, 11, 19, 20, 21 and 29 each once.

The clinical findings were not convincing. The average duration of the sulfadiazine treated cold was 8.1 days and that of the control 9.7 days. It can be appreciated that in a condition such as the common cold these figures are not significant. Of the 48 colds treated, 32 showed no recognizable secondary infection though they occurred in persons who usually suffered from complicated colds. Six persons developed sinusitis, bronchitis or both after the sulfadiazine treatment had been concluded. Five of the 6 had mild infections, but in 1 there was a moderately severe sinusitis and bronchitis (fig. 8), which lasted several days. Five patients had mild sinus and/or bronchial symptoms which developed during sulfonamide therapy. Five patients had irregular courses which could not be satisfactorily appraised. The patients were asked for their own opinions, and 34 expressed satisfaction with the therapy. Nine stated that they noticed no difference from previous colds, 1 was worse and 4 had no opinion

to offer. These personal opinions were interesting, but we know how misleading such information can be.

Figures 5, 6, 7 and 8 show the course of symptoms and changes in nasopharyngeal flora following sulfadiazine 1 Gm. three times daily for four days. The cases that are included represent the various types of response observed in the study. In the first case (fig. 5, G. F.) the onset was with a slight soreness of the throat, malaise and moderate rhinorrhea and sinus congestion. On the fourth day of the cold, when sulfadiazine therapy was started, in addition to the symptoms of onset there was also a moderate cough, and the nasopharyngeal culture showed a heavy growth which was almost pure hemolytic *Staphylococcus aureus*. Two days later (sixth day) the cold was much improved clinically but the nasopharyngeal culture still showed many colonies of hemolytic *Staphylococcus aureus* even though the blood sulfadiazine was 9.5 mg. per hundred cubic centimeters. Following this the symptoms disappeared almost completely; the nasopharyngeal culture showed a decided reduction in total organisms and almost complete disappearance of the hemolytic *Staphylococcus aureus*. This is the type of response that occurred in most of our cases.

Figure 6 (J. L.) shows a case that was not studied and treated until the tenth day of illness, when a very severe malaise, sore throat, rhinorrhea, sinus congestion and a moderate cough were present. The culture showed a heavy growth with many colonies of *H. influenzae* and a few colonies of hemolytic *Staphylococcus aureus*. The cold had progressed to the stage of second-

Fig. 4.—Key of symbols for symptoms and nasopharyngeal flora.

Fig. 5 (G. F.).—This patient shows a favorable clinical and bacteriologic response to sulfadiazine treatment.

dary infection. Following the institution of sulfadiazine therapy the symptoms subsided and the nasopharyngeal culture cleared rapidly.

Figure 7 (B. P.) again shows the course in a person treated by sulfadiazine 1.0 Gm. three times daily for four days. The onset this time was a slight sore throat

followed by severe rhinorrhea, moderate malaise and sinus symptoms. Treatment was instituted on the first day. The symptoms remained about the same for three days and then subsided slowly, disappearing except for a slight rhinorrhea on the seventh day. The

COMMENT

This study affords evidence that the sulfonamides do not shorten or alter the course of the uncomplicated cold. Furthermore, no striking benefits from sulfadiazine therapy were observed in the complicated colds. There is evidence, however, largely from the bacteriologic findings, that in selected cases secondary infections may be prevented by the oral use of sulfadiazine.

Our bacteriologic study revealed a consistent reduction in total organisms and number of pathogens cultured from the mucous membrane of the upper respiratory tract both in healthy persons and during colds following 1.0 Gm. of sulfadiazine three times daily. Cultures were made from the nasopharynx, which has the advantage of being relatively free from nasal and mouth contaminants, but what is true for the nasopharynx must be true also for other parts of the upper respiratory tract such as the trachea and sinuses. Bordley and his collaborators⁸ have reported similar bacteriologic findings following the local use of sulfadiazine, but their records indicate that satisfactory results are obtained only when the application is frequent enough to give an appreciable absorption. It would appear from our studies that the oral use of sulfadiazine is more dependable and simpler to administer than local application of the drug. Furthermore, the oral method is probably no more hazardous.

A very important factor in determining the value of sulfonamides in this field of therapy is the toxicity of the drug used. Sulfadiazine in the low dosage used in this experiment gives a satisfactory blood concentration but shows little clinical toxicity. The blood levels of sulfadiazine following the 3.0 Gm. daily dosage

varied from 3.4 to 10.5 mg. per hundred cubic centimeters with an average of 6.9 per cent. No serious toxic reactions occurred during the study. There was no nausea or vomiting, but there were two mild renal reactions, one with slight flank pain and many crystals in the urine, and the other with mild pain in the lower part of the abdomen radiating to the scrotum, with a few red blood cells in the urine. One other patient showed a sudden drop in the white blood cells at the time the sulfadiazine therapy was completed, but a few days later

the blood count was normal. The evidence from this study and other studies¹⁵ is that toxic reactions on this dosage of sulfadiazine are rare but that

Fig. 6 (J. L.).—Patient was treated late in his infection with sulfadiazine. Excellent clinical and bacteriologic response.

nasopharyngeal culture at the time therapy was instituted showed a few pneumococci and a very few colonies of *H. influenzae*; these disappeared after treatment was started and the total number of organisms was considerably decreased. When treatment was discontinued the number of organisms increased and a few pneumococci were again found, although there was no return of symptoms. This person ordinarily has a long course of sinusitis following a cold (two to four weeks).

Figure 8 (S. M.) is the graph of a case of acute coryza which started with an irritated throat followed by malaise, rhinorrhea and sinus congestion. Treatment was started on the second day, when the rhinorrhea was severe and there was also an irritative cough. The nasopharyngeal culture on this day showed a heavy growth with a few colonies each of beta hemolytic streptococcus, *H. influenzae* and hemolytic *Staphylococcus aureus*. With the four days of treatment the course was somewhat favorable, the nasopharyngeal culture showing only a few organisms, the hemolytic streptococcus and *H. influenzae* disappearing entirely, and the symptoms being slightly less in evidence. With cessation of sulfadiazine treatment, however, the hemolytic streptococcus returned and type 20 pneumococcus appeared in increasing numbers. At the same time the symptoms became aggravated and the patient developed a severe sinusitis and bronchitis. The suggestion in this case is that if therapy had been continued for a longer period the secondary infection would have been prevented.

Fig. 7 (B. P.).—This patient shows excellent clinical and bacteriologic response to sulfadiazine but rapid reappearance of bacteria after discontinuance of the drug.

they can occur and must be guarded against. There is also the possibility of minor chronic pathologic changes¹⁶ occurring with sulfonamide therapy that may become significant following repeated courses of treatment. Finally there is the possibility of creating sulfonamide resistant organisms,¹⁷ a condition which up to the present has had only a slight clinical significance in respiratory infections but which might be highly important if the sulfonamides are used in frequent short courses.

During the past few years a number of reports on acquired hypersensitivity to sulfonamide drugs have appeared in medical literature. The most recent and comprehensive of these reports is that of Longcope.¹⁸ It would appear quite well established that a few individuals acquire hypersensitivity to sulfonamide drugs and show their reaction by fever, skin rashes, nausea and vomiting and other manifestations. The occasional occurrence of this phenomenon presents another reason

there are the cases of asthmatic bronchitis, pneumonia secondary to bronchiectasis, repeated otitis media or recurrent severe sinusitis in which sulfonamide drugs under similar control should be thoroughly tested.

SUMMARY

1. Seventy-two colds in 66 different persons were followed clinically and bacteriologically; 48 received sulfadiazine 3.0 Gm. daily by mouth for four days, while 24 served as controls.

2. Following sulfadiazine, the nasopharyngeal flora as observed by serial cultures showed a uniform decrease in total number of organisms and a check in the growth of pathogens.

3. The clinical course of the treated colds showed no striking difference from that of the controls; however, there appeared to be some amelioration of symptoms due to control of secondary bacterial infection.

4. As a result of this study, we are opposed to the routine use of sulfonamides in the treatment of the common cold but would favor their use in a few selected cases as a protection against severe secondary infection.

FEVER THERAPY IN OPHTHALMOLOGY

FREDERICK C. CORDES, M.D.

SAN FRANCISCO

One of the more recent developments in ophthalmic therapeutics has been the use of fever therapy for acute lesions of the eye and its adnexa. The pyrexia has been produced by three methods, the parenteral injection of nonspecific proteins, the use of malaria and physical means. There are many reports in the literature of the use of fever therapy in ophthalmology. It seems worth while to review the subject in an attempt to evaluate the various methods and to determine the safest and most efficacious one. It would appear that several of the methods have a more or less specific place in the ophthalmologist's armamentarium.

The use of fever therapy, according to Gifford,¹ began with observation of the beneficial effect of intermittent infection with accompanying fever in various diseases. Only recently Reginis² and Delanoe and Sedan³ observed definite improvement in trachoma following pneumonia, typhoid and malaria. Cases have also been observed in which the use of diphtheria antitoxin produced an apparently beneficial effect in diseases other than diphtheria. Such observations in the past formed the basis on which fever therapy developed.

The mechanism of the beneficial effect of this therapy has been described recently by Sanders.⁴ He pointed out that in fever therapy a prompt effect is exercised on the autonomic nervous system; in the splanchnic area a vascular dilatation takes place, with contraction of the peripheral vessels causing a chill. This is soon followed by a capillary dilatation. With the rise of temperature there seems to be a general stimulation of cellular activity as shown by the changes in the blood. There is a short period of leukopenia followed

Fig. 8 (S. M.).—Acute coryza and sinusitis. Patient showed good bacteriologic response to sulfadiazine with only slight clinical improvement. With discontinuance of drug, pathogens again became numerous in the nasopharyngeal cultures, and patient developed a severe sinusitis and bronchitis.

why sulfonamide drugs should not be used as a routine in the common cold.

This report is only a preliminary one, but we present it chiefly because we believe that it offers a method for further study of the sulfonamides. On the basis of our experience we would restrict the use of the sulfonamides to a very few selected cases, such as those in which the history reveals an almost invariable and severe secondary infection following the cold. For example,

by leukocytosis, with the white cell count from 12,000 to 15,000, in which polymorphonuclear cells predominate. There is definitely a rise of antibody content of the blood, from either increased formation or increased circulation of antibodies from the tissues. Peterson⁵ was able to demonstrate that there is an increase in the blood content of proteolytic and lipolytic enzymes that break up the bacteria and their toxins into harmless products. This is accompanied by an increased cell permeability by which antibodies more readily penetrate the cells from the blood stream. Von Szily⁶ found that one of the local reactions of the eye consists of an active hyperemia of the whole uveal tract accompanied by infiltration with lymphocytes. Brown⁷ was able to show that the antibody content of the aqueous is increased. It seems probable according to Duke-Elder⁸ that the main effect is a general one whereby the whole mechanism of immunity receives a stimulation that produces greater activity.

The role of the fever is still doubtful; it may be only an unimportant manifestation of the reaction or it may be the cause of the increase in cellular activity. The vasodilatation may also play an important part. According to Duggan⁹ the effect of the bacteria and their toxins as well as the effect of other stimuli is the production of local ischemia with resultant pathologic changes. This newer conception of pathologic physiology is based on the work of Ricker,¹⁰ who stated the belief that the underlying mechanism of both inflammatory conditions and hypertension is a neurovascular upset. In inflammatory conditions bacteria or other stimuli at first set up a vasoconstriction of all terminal vascular segments. The capillaries rapidly become fatigued and relax, producing a fatigue paresis. Thus a dilatation of the capillaries is present, associated with a sustained constriction of the arterioles, which results in a slowing of the blood stream in the capillary bed. With this dilatation the capillaries become more permeable, possibly owing to anoxemia or to opening up of stroma between the capillary endothelial cells. Thus it is apparent that, depending on the degree of slowing of the blood stream and therefore of capillary dilatation, there will be progressive degrees of exudate. In the milder cases this will consist only of plasma and fibrin, in the less mild it will contain white cells and in the severe cases it will contain red cells. There are many causes for the vasospasm, among them the toxin of bacteria. On this basis, increasing the oxygen available to the area by relief of vasospasm seems rational. Gifford and Marquardt¹¹ and others have called attention to the fact that typhoid vaccine therapy acts as a vasodilator. This explains the beneficial effect of vasodilators, such as sodium nitrite, when combined with typhoid vaccine in the treatment of an acute fundus lesion that appears to have an angiospastic basis. Thus it seems feasible to assume that, in addition to the changes caused in the blood picture, the vasodilator factor in fever therapy may be important.

Both Gifford¹ and Sanders⁴ have pointed out that because the fever is the most obvious and easily recorded manifestation it is the best criterion as to the severity of the reaction. While therapeutic results are usually in direct relation to the degree of reaction obtained, one must remember that at times there seems to be a beneficial effect without the production of appreciable fever.

Having discussed the changes that take place in the body during fever therapy, I shall consider the various forms of fever treatment used.

PARENTERAL INJECTION OF FOREIGN PROTEINS

Although foreign protein therapy has lost some of its former popularity, particularly since the advent of the sulfonamide drugs, it is still used for such conditions as typhoid, pneumonia, puerperal sepsis, arthritis, pelvic inflammation, syphilis of the central nervous system, other diseases of the central nervous system (such as multiple sclerosis), peptic ulcer, certain infections of the skin and some vascular conditions (such as thromboangiitis obliterans⁴).

Foreign protein therapy has been found useful in the treatment of many ophthalmic diseases, including acute conjunctivitis, gonorrheal ophthalmia, phlyctenular keratitis, interstitial keratitis, corneal abscess, corneal ulcer, acute iritis, chronic iritis, uveitis, post-operative iridocyclitis, disease resulting from a wound of the eyeball, scleritis and sympathetic ophthalmia. It has also been advocated for retinitis, choroiditis, optic neuritis and retrobulbar neuritis. Slavik¹² reported some improvement in retinitis pigmentosa after milk and typhoid therapy, while Kapuscinski¹³ produced good results in herpes zoster and juvenile recurrent hemorrhage of the vitreous. Delanoë and Sedan³ reported significant improvement in acute trachoma. Foreign protein should be given early in the disease, before permanent damage has been done to the tissues involved. There can be little doubt that foreign protein therapy is of greater value for inflammation in the uveal tract, particularly the anterior part, than in any other tissue of the body.

The ideal reaction according to Lewis¹⁴ consists of a moderate chill with a temperature of about 103 F., which falls quickly and after twenty-four hours returns to normal. If it is desirable to continue the treatment another injection should not be given until the temperature returns to normal or its previous level. It is advisable to wait twenty-four hours at least, as not infrequently there is a secondary rise of temperature after twelve hours. Lewis said that the second dose should be given forty-eight hours after the initial dose and that too short an interval caused the death of 1 of his patients rather than large doses (50 million and then 100 million organisms). The output of urine should be checked after the injection. Hench¹⁵ recommended that no food be taken two to four hours prior to the injection.

Severe reactions are rare but do occur. The size of the dose is not the only factor in their production, as they have been known to follow even very small doses.

Treatment of severe reactions has been discussed a number of times. Cold sponging and packing in iced

sheets is indicated. For anaphylactoid phenomena Hanzlik and Karsner¹⁶ recommended the intravenous use of atropine and epinephrine. Howard¹⁷ advised large doses of digitalis by hypodermic when a severe reaction occurs with signs of circulatory collapse. Hench¹⁵ said that renal insufficiency and oliguria demand the administration of diuretics intravenously.

Foreign protein therapy is not without risk. There are definite contraindications to its use. Cecil¹⁸ listed the more important ones: advanced arterial, renal or cardiac disease; allergic states or conditions of pronounced protein sensitivity, such as angioneurotic edema and giant urticaria; states of extreme exhaustion following prolonged illness; pulmonary tuberculosis, active or quiescent; hemorrhagic conditions, such as hemophilia and bleeding ulcers; chronic alcoholism, in which it may produce delirium tremens, and severe nervous sensibility, such as that seen in hyperthyroidism. Hench¹⁵ added chronic infections of long duration with dissemination to several sites; the period within fourteen days after an operation, for hemorrhage has occurred occasionally when vaccine was given within ten days after tonsillectomy or a minor pelvic operation; pregnancy, for fear of inducing hemorrhage and uterine muscular contractions, and rheumatic fever with acute or decompensated carditis and diabetic acidosis. Raulston¹⁹ stated that foreign protein therapy in the aged usually does not produce very favorable results.

In discussion of the various substances used to cause the reaction, the classification of Sanders¹ will be followed.

Native Proteins.—The successful and widespread use of foreign protein therapy in ophthalmology dates back to 1915, when it occurred to Schmidt²⁰ of Prague to use cow's milk to induce fever. There are earlier isolated instances of the use of foreign protein in the treatment of certain conditions, but Schmidt's work started this type of therapy in ophthalmology. His work was quickly followed by that of Saxl,²¹ Muller and Thanner,²² Purtscher²³ and many others. For a number of years this form of therapy was widely used. According to Muskat²⁴ its advantage is that milk is a universal product and constant in its chemical composition. He stated the belief that the good reaction was due to its complexity and the variety of enzymes in its cleavage products.

The usual method is to inject intramuscularly 8 to 12 cc. of fresh cow's milk (for patients of average weight) that has been sterilized by being boiled four minutes and has then been cooled. This period of boiling was chosen as being long enough to destroy bacterial contamination and yet not long enough to inactivate whatever might be the active component contained in milk. (In infants, for example in the treat-

ment of ophthalmia neonatorum, 1 to 2 cc. is sufficient to produce a temperature of 100 to 103 F.) In most instances the injection is followed by a rise of body temperature, with chill and malaise, which usually subsides within eight hours. The temperature may rise to 100 to 103 F. or, in some instances, the injection may produce no reaction even though given in a similar manner and in a comparable case. Barkan and Nelson²⁵ were able to show that the shock-producing properties of milk depend in a large part on the bacterial count of the milk. El-Bakly²⁶ stated that the poorer grades of milk give better results because of the higher bacterial count. In the use of milk injections at the University of California, a reaction was not produced until milk was obtained from the corner grocer and incubated for twelve to twenty-four hours before injection. The hospital was supplied with certified milk, which has a low bacterial count (less than 10,000 per cubic centimeter).

While the literature contains many reports of successful reactions with milk, there were many failures because of this factor. In addition, the milk had to be boiled and cooled, which was an inconvenience. Hematoma and local abscesses were not infrequent. Because of the unreliability of the reactions observed in this country and because of the complications mentioned, milk injections were not used as long or as extensively here as abroad. In discussing this subject with Pillat in Vienna in 1935 he stated that milk injections were not feasible in America, as the milk was too clean. As a result of these disadvantages other methods have in general come to replace the use of milk to induce fever in adults.

That milk was not entirely satisfactory is evidenced by the fact that many substitutes for milk were put on the market.

The caseins received a good deal of attention for a time. Wick²⁷ used yatren-casein, caseosan, alobintin, perprotasin and aolan and found that, while they were useful in treating acute ocular conditions, they were not as effective as milk. Triebenstein²⁸ also reported beneficial results with yatren-casein in some of the chronic inflammations of the eye but found milk injections were more effective. Gaston²⁹ found aolan much less effective than milk, while Jickeli³⁰ obtained good results from aolan. While there are numerous reports of the use of these caseins, they are as a rule not very encouraging.

Egg albumin was also used. The report of Frydman³¹ is typical. He used cibalbumin, which contains 1 per cent egg albumin, and expressed the opinion that it produced mildly satisfactory results. He concluded that protein therapy by intramuscular injection of cibalbumin presents no danger to the general organism or the eye and that it was easily applicable to ambulatory patients.

Haass³² pointed out that von Szily⁶ demonstrated histologically that parenteral injection of nonspecific

protein results in an inflammatory reaction in the eye followed by a phase in which inflammation is retarded. He said that it would be desirable to find agents which would directly produce the second, or anti-inflammatory, stage, and he found protasin and perprotasin to be such agents.

Protein Split Products.—Protein split products, including peptone albumose and the proteoses, have all had their advocates but have never been used extensively. Nolf³³ injected 5.6 cc. of a 10 to 100 peptone solution into the vein and repeated the injection every hour. He obtained beneficial results in ocular complications occurring during typhoid, typhus and septicemia. Narog³⁴ found pepsin injected subconjunctivally useful in the treatment of trachomatous lesions of the eyelids and turbidity of the vitreous.

Tissue Extract.—Rinaldi,³⁵ injecting bovine uveal pigment in 10 cases of sympathetic ophthalmia, found slightly increased sensitivity. He said this treatment was distinctly beneficial but that the action was not like that of foreign protein, for it was only when all general and local reactions were avoided that the decided improvement resulted.

Serums.—As Clegg³⁶ has pointed out, various types of serum have been employed in the treatment of ocular lesions. They include the serums of Roux and Behring, Deutschman's yeast serum, auto serum, normal horse serum and antitoxin. Only the more frequently used ones will be discussed here.

As early as 1904 Darier,³⁷ noting the excellent results of diphtheria antitoxin, experimented with it in the treatment of conditions other than diphtheria. At about the same time Rohmer³⁸ used autoserum obtained by raising a blister in the scapular region, drawing off the serum and injecting it under the skin or subconjunctivally. Another method employed is to withdraw 5 to 10 cc. of blood from the patient's vein and either inject the whole blood intramuscularly immediately or allow the clot to separate and then inject the serum. The results have been claimed to be superior to those of other methods. Jacovides³⁹ used autoserum in 150 cases of corneal ulcer, with good results in 140. Wick²⁷ and others, in comparing the effects of autoserum with those of other proteins, found the results to be no different except that fever occurred less often with autoserum. Mata⁴⁰ reported 11 cases of tuberculous iridocyclitis in which he withdrew the aqueous and injected blood into the anterior chamber. He found that with this method the condition cleared more rapidly than in control eyes. As Gifford¹ pointed out, there seems to be no reason for ascribing to autoserum the remarkable advantages claimed by some authors, while the conditions of administering it make it much less convenient than milk or typhoid vaccine.

Antidiphtheria Serum: The use of antidiphtheria serum has been advocated by a number of authors.

Key⁴¹ used 2,400 to 3,200 units every two to three days in the treatment of corneal disease, including hypopyon keratitis and serpiginous ulcer, of infection of the anterior segment of the eye and of panophthalmitis. Verhoeff⁴² reported some remarkable results in the treatment of sympathetic ophthalmia. According to the age of the patient, he used from 5,000 to 20,000 units daily for a week, eliminated the treatment the following week and then repeated it for two to three weeks.

Horse Serum: Scarlett⁴³ stated the belief that in diphtheria antitoxin it was the horse serum rather than the antitoxin that was the effective element. He used pure horse serum in the treatment of acute iritis and concluded that of the foreign proteins it gave the most definite reaction and also the greatest relief from symptoms.

The disadvantages of using pure horse serum or antitoxins are obvious. An intradermal test must be made for sensitivity to avoid the occurrence of dangerous or fatal anaphylactic shock. The test apparently is not infallible, as Liebman⁴⁴ reported anaphylactic shock following the use of antidiphtheria serum in a patient who had a negative intradermal reaction before injection of the serum. Most authorities agree that horse serum has the objection of sensitizing the subject and producing serum reactions. With repeated doses the non-specific reactions may become more severe, even when the injections are made within the period usually allotted before sensitization will occur. Great caution should be exercised in its use, especially since there is no conclusive evidence that the temporary effects obtained are worth the dangers risked by its injection. The one disease for which its use may be justified is sympathetic ophthalmia, in which diphtheria antitoxin apparently is useful.

Vaccine.—While various vaccines have been employed, the use of typhoid vaccine intravenously is the method most widely advocated for fever therapy. The indications for its use are those given for other types of foreign protein fever therapy.

Typhoid vaccine was first used intravenously by Kraus and Mazza⁴⁵ in Argentina about 1912. It was first given intravenously as a nonspecific protein for fever therapy by Miller and Lusk⁴⁶ in the treatment of chronic infectious arthritis. It is employed for many diseases, particularly of the joints, skin and eyes. This discussion will be limited to its use in ophthalmology.

The preparation usually employed is the standard typhoid-paratyphoid A and B vaccine. The injection is given intravenously, and the dose varies from 5 million to 100 million organisms, depending on the individual ophthalmologist. Thirty million is the amount usually recommended as the initial dose. Sanders⁴ recommended 50 million as the initial dose for men and 35 million for women. This is increased to 40 and then to 50, 60, 70 or 100 million, depending on the preceding reaction. The usual reaction consists of a chill, fever, mild headache, general malaise and mild gastrointestinal

upset. The temperature varies a good deal with the individual patient and the vaccine used. Allen⁴⁷ found that the average temperature obtained after an average initial injection of 53 million organisms was 101.8 F. After the second injection, in which an average of 80 million organisms was used, the temperature averaged 102.7 F.

The use of typhoid vaccine is not entirely without danger, and, while they are rare, unusual reactions do occur. Hench¹⁵ reported 3 deaths among 2,500 patients given 10,000 injections at the Mayo Clinic. Sudden death has also been reported by Russel,⁴⁸ Lemoine,⁴⁹ Patton⁵⁰ and others.

A focal reaction, or activation of the local lesion, immediately after an injection of foreign protein is a well recognized phenomenon but is usually transitory. It has been reported in the treatment of diseases of the eye by Benedict,⁵¹ Tobias,⁵² Lockhart⁵³ and others, but it is so rare in such treatment that it may be disregarded. The contraindications to fever therapy in general, previously listed, also apply here.

After the death in San Francisco of 2 young and apparently healthy persons who had received typhoid vaccine for ocular diseases in 1935, my co-workers and I at the University of California Hospital modified our dosage. According to the age, size and general condition of the patient, it is our routine to start intravenous injections of typhoid vaccine with a dose of 5 to 7 million killed organisms. This produces a moderate rise of temperature in one to two hours lasting two to four hours and producing relatively little discomfort. The temperature at times goes up to 103 F. but usually averages about 101 to 102 F. The following day the dose is increased to 7½ to 9 million organisms unless there has been a secondary rise of temperature, in which case the second dose is delayed twenty-four hours. On the third day 9 to 10 million organisms are given and on the fourth 12 to 15 million. Thus it is possible to produce fever and prolonged vasodilatation over a period of four days without any great discomfort to the patient. In a few instances when the patient does not respond to these doses the amount is increased to 25 million. It must be remembered that there is considerable variation in the potency of commercial vaccines regardless of their reported bacterial count and that doses must be varied accordingly.

Having used the smaller doses since 1935, we have found that the average temperature after the first injection has been 101.5 F., after the second 102.1 F., after the third 101.8 F. and after the fourth 101.4 F. These figures are almost identical with the temperatures observed by Allen,⁴⁷ who after an average dose of 53 million organisms found an average temperature of 101.8 F. and after a second average injection of 80 million organisms an average temperature of 102.2 F. In general we feel that vasodilatation is probably an important part of the beneficial effect derived from fever therapy, except in the treatment of syphilitic patients, and it is our opinion that the smaller doses

of typhoid vaccine, which cause less severe systemic reactions, are as efficacious as the larger doses formerly employed and make prolonged vasodilatation possible. Hench¹⁵ also favored the smaller doses and said that, "although large doses may be tolerated, small doses if accompanied by an adequate reaction seem preferable, since as beneficial results seem to follow the use of small doses as the large doses."

The method of dosage is as follows: We have used Cutter Laboratories (Berkeley, Calif.) typhoid vaccine, which contains 500 million bacilli per cubic centimeter. With a tuberculin syringe 0.1 cc. of this solution is drawn up; it is then diluted to 1.0 cc. with isotonic solution of sodium chloride or distilled water. With this solution 0.1 cc. contains 5 million, 0.15 cc. 7½ million, 0.24 cc. 12 million, 0.30 cc. 15 million organisms, and so on.

In addition to the usual conditions treated by fever therapy, we have found typhoid vaccine therapy valuable in the treatment of acute fundus lesions when a rapid prolonged vasodilatation is desirable. It has also been used in the treatment of acute fundus disease by Gifford and Marquardt¹¹ and Benedict and Rucker.⁵⁴ It can be combined with the use of sodium nitrite or some other form of vasodilator.

Of the means of inducing fever, typhoid vaccine is the most useful and the most widely employed in ophthalmology because of the consistent reaction and ease of use. In spite of occasional untoward reactions, there are acute ocular lesions that demand the risk because of the probable benefit and the hope of preservation of vision in what might otherwise be a hopeless situation.

Typhoid H Antigen.—The antigen in washed flagellums of typhoid bacilli, known as typhoid H antigen, induces a less violent reaction than typhoid vaccine and has been advocated as a substitute. The antigen is prepared by adding 0.1 to 0.2 per cent solution of formaldehyde or 0.5 per cent phenol to a broth culture or a saline solution suspension of a motile strain of *Eberthella typhosa*. Its uses and dosage are for all practical purposes identical with those of typhoid-paratyphoid vaccine. The principal advantage of typhoid H antigen is that it produces a satisfactory rise of temperature without a great deal of chill. It has been said that the chill phase of nonspecific foreign protein therapy is conducive to thrombosis and that its elimination adds materially to the safety of the method. This antigen has never obtained widespread popularity.

According to Klauder and Robertson,⁵⁵ after an intravenous injection the constitutional reaction is not pronounced, so that ambulant patients may be treated. They employed the method in 30 children with active interstitial keratitis attending the Wills Hospital, Philadelphia, the youngest patient being 6 years of age. They found that the chill appeared one hour after the injection, lasting usually about half an hour, and the temperature rose to 102 to 104 F., becoming normal in six to eight hours. Patients in the hospital as well as those attending the clinic were treated. No serious untoward reactions were produced. They found that different lots of typhoid H antigen varied in their ability to produce reactions and different patients varied in the degree of their reactions from the same lot of

vaccine. Sanders⁴ stated that it can be used in the office and that it causes prompt rise of temperature but usually without chill. Brown⁵⁶ used typhoid H antigen preoperatively in all cases of cataract to prevent inflammation. From fifty to seventy-two hours before operation the patient was given intradermally 1 minim (0.06 cc.) of a solution of typhoid H antigen (25 million organisms per cubic centimeter). If there was no local reaction within twenty to thirty minutes, a solution containing 15 million organisms was injected intravenously. This was done at the office and the patient instructed to go home because a reaction might ensue in four to eight hours.

When an eye was perforated accidentally in any manner, typhoid H antigen was immediately given intravenously after a negative cutaneous reaction. If the wound was purely ocular, preference was given to the antigen rather than to antitetanus serum unless there was definite reason to fear exposure to tetanus.

In our limited experience with typhoid H antigen we found that the action and reaction were much like those of typhoid vaccine.

Mason,⁵⁷ in an endeavor to obtain good results from foreign protein without shock, used an antigen which contained *Streptococcus haemolyticus* with *Staphylococcus aureus* and *Staphylococcus albus* and which had a very low protein content and was nontoxic. He used it in 8 cases of uveitis with excellent results. No patient showed shock or chill, and the temperatures did not register over 0.5 degree (F.) above normal. No further reports of this treatment have appeared.

Spirochetic vaccine of Hilgermann was used by Charamis⁵⁸ in the treatment of ocular syphilis. There were 3 patients with interstitial keratitis, 1 with oculomotor and facial nerve paralysis and 1 with choroiditis. Those with interstitial keratitis particularly were benefited. He said that vaccine therapy is valuable in slowly evolving cases and particularly as a complement to chemotherapy. Its use has been so limited that it does not require serious consideration.

Bacterial Extracts.—There are times when a milder fever therapy is desirable or when it is not practical to hospitalize the patient. Under these conditions Coley's mixed toxins⁵⁹ can be given in the clinic or office and the patient sent home. We have found this preparation to be a useful addition in fever therapy. Relatively little has been written regarding its use in ophthalmology aside from an article by Levine⁶⁰ in 1931. It is a mixture of toxins derived from killed cultures of *Staphylococcus erysipellatis* and *Bacillus prodigiosus*, which are grown separately, then mixed and finally diluted to a definite strength as determined by the percentage of proteins contained.

The adult dosage is 3 minims, with proportionately less for children. Deep intramuscular injections are given into the arm with the ordinary tuberculin syringe. Levine⁶⁰ found that in only 2 cases was it necessary to give 4 minims to obtain the desired reaction. The reaction sets in four to five hours after the injection, which allows the patient time to reach home before it starts. There is usually a chill that lasts fifteen to thirty minutes and is followed by a rise of temperature from 100 to 102 F. which may last ten or more hours.

There is no headache or vomiting and very little discomfort. It is important, as Lewis¹⁴ has pointed out, that the patient remain in bed until the reaction is entirely over. There may be some redness in the arm at the site of the injection, but it disappears quickly. Coley's mixed toxins have been found useful in the treatment of mild acute inflammation of the uveal tract, corneal ulcer and the milder postoperative iridocyclitis. It is well to remember this preparation as an inexpensive, easily administered means of fever therapy that can be used without hospitalization and produces a fair fever reaction.

Omnadin⁶¹ consists of a mixture of protein substances obtained from nonpathogenic bacteria, various animal fats and lipoids derived from bile. It is given in 2 cc. doses intramuscularly daily or at times twice a day. It causes no temperature reaction and therefore strictly speaking does not belong in a discussion of fever therapy. As Sanders⁴ has stated, it does, however, produce some leukocytosis and a rise in the antibody content of the blood. It causes no untoward reaction and has been found useful in those cases in which the physical condition does not warrant the severer types of foreign protein therapy, for example iridocyclitis following cataract extraction in older patients. Wick²⁷ found that, while it did not produce fever, as did milk, it did cause an improvement in the inflammatory process.

USE OF MALARIA

In 1918 Wagner-Jauregg⁶² introduced malaria as a treatment for dementia paralytica, and, because of the remarkable results obtained, its use in the treatment of syphilitic conditions became rather widespread. Heat is a spirocheticide. The virulence of *Treponema pallidum*, studied in rabbits, was reduced when subjected to a temperature of 104 F. The thermal death point is slightly higher. This fact had led to use of the higher temperatures in fever therapy of syphilitic conditions.

In malaria fever therapy, *Plasmodium vivax*, the parasite of the benign tertian type, is used. A complete physical examination is necessary before the treatment is started to rule out the contraindications to fever therapy. It is not to be used for patients under 11 years of age, as typhoid therapy is as effective in the younger age group and malaria therapy is not well tolerated by children. According to Klauder and Robertson⁶³ Negroes are usually immune, so that it cannot be used in that race. To induce the fever 5 to 10 cc. of blood from a patient with malaria is withdrawn and injected into the vein of the recipient. With the onset of the fever the blood pressure should be taken twice daily and the blood count twice a week. If the systolic blood pressure drops below 90 between paroxysms and if the red cell count is below 2,000,000, the patient's condition is considered serious. In uncomplicated cases eight to ten chills are permitted before the malaria is terminated by giving quinine sulfate 0.09 Gm. three times a day for five to seven days. The local treatment to the eye is given as usual. During the treatment the patient is put on a high caloric diet and fluids are forced. The urinary output is watched, as oliguria necessitates suspension of the treatment. With this form of fever therapy the temperature will rise to 105 or 106 F.

Ambler and Van Cleve⁶³ stated the belief that this treatment is beneficial in interstitial keratitis. Clark⁶⁴ concluded that the malaria treatment may arrest syphilitic invasion of the optic nerves and preserve vision. The McIntyres⁶⁵ said that syphilitic optic nerve atrophy should be treated with malaria. In their opinion malaria has several practical advantages over heat therapy. It is less expensive and requires less time, less equipment and less technical assistance. The number of patients treated is not limited by the units. In addition, the biologic antagonism of malaria to syphilis is of longer duration and biochemically more far reaching than that exerted by heat alone. There are many other favorable reports in the literature.

In spite of the favorable reports there are serious inherent faults. The induced infection may produce great damage. There are always pronounced fatigue and wasting away as a result of the treatment. The mortality in different series varies from 1 to 10 per cent. The fever-producing properties are not constant, and 10 per cent of the injections are unsuccessful. The difficulty of maintaining properly attenuated strains of the virus also must be considered. As Hambresin⁶⁶ stated, it must be remembered that a patient inoculated with malaria can infect anopheles that would transmit the malaria. Lastly, malaria treatment requires from two to four weeks of hospitalization. From this it is apparent why even for syphilitic conditions malaria treatment has been rather generally discarded in favor of other types of fever therapy.

PHYSICAL MEANS

Several physical methods have been used to produce fever therapy. They have the advantage that the fever can be controlled as to time, amount and duration.

High Frequency Methods.—According to Coulter⁶⁷ the production of heat in the body tissues with high frequency currents insufficient in amount to harm or destroy tissues is called medical diathermy. There are three different methods of application.

Diathermy: This is usually construed to mean the use of the ordinary diathermy machine, which operates on a frequency of about 1,000 kilocycles (300 meters). It is applied by ordinary metallic electrodes held in contact with the body by a jacket or binder. The patient is covered with blankets or encased in an insulating bag. Neymann and Osborne⁶⁸ found it possible to induce fever with diathermy. Neymann and Koenig⁶⁹ reported that diathermy-induced fever produced a higher rate of remission in patients with dementia paralytica than was obtained in a comparable series of patients treated with malaria or rat bite fever. Other writers have given equally encouraging reports. The indications for the use of diathermy in ophthalmology are by no means well established. It has been used to give relief from pain in herpes zoster and in the treatment of corneal ulcer and a few other conditions. According to Gifford⁷⁰ one condition in which it has

been successfully used is orbital cellulitis which does not localize well enough so that incision is effective. A large sheet of tin or aluminum is molded to cover the region, this being used as the active electrode. The larger the active electrode the less the heat that is generated at any one point; thus a large electrode eliminates heat that is "dangerous to the eye, provided that only 200 to 400 milliamperes be employed, and that the current be reduced whenever the heat becomes uncomfortable to the patient."

Radiothermy (Short Wave Therapy): The radiotherm is operated at about 10,000 kilocycles (30 meters) with tube oscillators. The patient is placed in a high frequency field between the two large plates of the radiotherm, without active contact, heat being produced by dielectric losses and induced currents. Bishop, Lehman and Warren⁷⁰ emphasized that in treating a patient by this method the moisture must be removed to prevent burns. They employed a cabinet in which lamps maintained the temperature after the current was turned off. With this apparatus, according to Hambresin,⁶⁶ one produces a temperature of 105 F. in a patient weighing 70 Kg. in half an hour. After this temperature is reached it is maintained for four hours. This treatment demands rigorous supervision by a nurse-technician during the application and the repose period that follows. According to Bierman⁷¹ there is evidence that short wave therapy does have some bacteriostatic effect in various tissue infections. In addition to elevation of the temperature the biologic reaction of tissues is important. This includes hyperemia, with its greater blood and lymph flow, together with changes in local metabolism and local immunity. One of the real dangers of this method of treatment is burns of the skin. Its use has been reported in the treatment of chronic uveitis, vascular fundus disease, acute progressive infection and syphilitic optic nerve atrophy, but observations of treatment of ocular disorders are rare. There is no record of damage to the eye from the local use of short wave therapy. Short wave is an effective agent for creating heat within the eye. The work done in this field is recent and the number of cases too few to permit a conclusive statement as to the value of short wave therapy.

Inductothermy: In this method of fever therapy an electromagnetic field is produced with the patient acting as resistance. Heat is therefore induced internally. The technic, according to Weeks and Morris,⁷² is simple. The patient can be treated in bed with a canvas support replacing the springs.

The induction cable is laid in a loop on the bed. Padding is placed between and around the loop to provide a level surface. The patient is placed in a water-proof canvas bag with a wood cradle inserted between patient and bag so as to permit a certain degree of mobility.

The pulse rate, respiratory rate and rectal temperature are recorded every five minutes.

In general, old age, organic lesions of the cardiovascular system, nephritis, anemia and pronounced emotional and nervous instability are considered contraindications for this type of therapy.

A temperature of 106 F. is produced and maintained for from four to six hours and at times for a total of twelve hours.

72. Weeks, Webb W., and Morris, S. A.: Induced Hyperpyrexia in Ophthalmology, Am. J. Ophth. **21**: 664 (June) 1938.

Weeks and Morris⁷² from their observations concluded that the therapy appears to be valuable in the ocular complications of gonorrhea, in iritis, in superficial punctate keratitis and in scleritis. They found it of little value in trachoma, syphilitic uveitis and interstitial keratitis.

Kettering Hypertherm.—A wide variety of other physical means has been employed to produce hyperpyrexia, including hot baths, hot air, electric blankets and various forms of radiant energy, such as electric lamps in a cabinet. Use of a radiant energy cabinet is the easiest and most convenient method. There is no apparent difference in the clinical effects from various types. Of the air conditioned cabinets, the Kettering hypertherm is the best known and most widely used.

The following description is from Kendall, Webb and Simpson's⁷³ article: The Kettering hypertherm is an insulated cabinet in which the nude patient lies with the head extending outside the cabinet. There is sponge rubber insulation around the neck where it projects through the cabinet. The patient lies on an air mattress supported by a boxlike bed which is rolled in and out of the cabinet at will. In the rear of the apparatus is a small insulated fireproof compartment for the air conditioning apparatus. The temperature of the air, recorded on a dry bulb thermometer, is controlled by a thermostat. The humidity is controlled by a "humidistat." The velocity of air within the cabinet is controlled by fixed speed blowers.

Induction of fever is accomplished by the circulation of heated air from air conditioning apparatus and from the heated mattress, together with the prevention of radiation and evaporation from the body by the cabinet.

With this method a rectal temperature of 105 F. or over is usually reached in from forty to sixty minutes. By adjusting the air temperature and humidity one may maintain the body temperature at the desired level. At the completion of the treatment defervescence is produced by streams of cooler air. The body temperature usually returns to normal in from thirty to forty minutes.

Culler and Simpson⁷⁴ regarded advanced age, myocardial insufficiency and aortic aneurysm as contraindications. McGavic⁷⁵ added to these renal disease, active tuberculosis and diabetes if not controlled. Controlled diabetes is not considered as a contraindication.⁷⁶

Constant observation by an especially trained physician and nurse-technician is regarded as an essential feature of the fever therapy. During the treatment water and cool 0.6 per cent saline solution are given by mouth to maintain the chloride balance. Mental and physical preparation for the treatment is also carried out in detail. Culler and Simpson⁷⁴ gave most of their patients ten weekly treatments of five hours each at a rectal temperature of from 105 to 106 F.

Culler and Simpson treated 58 patients with ocular syphilis with approximately fifty hours of fever. Interstitial keratitis seemed to be definitely benefited. In each of 10 cases of exudative uveitis prompt clinical improvement became apparent. Improvement was noted in optic neuritis and neuroretinitis, active choroiditis and optic nerve atrophy. McGavic⁷⁵ found the treatment most efficacious in gonorrheal conjunctivitis and

syphilitic iridocyclitis. Hasler and Speker⁷⁷ found it effective likewise in gonorrheal ophthalmia. Whitney⁷⁸ reported beneficial results in corneal ulcer. Prati⁷⁹ reported a case of syphilitic optic nerve atrophy which improved under pyretotherapy. There are similar reports from other authors. Krusen and Elkins⁸⁰ emphasized that the combination of fever therapy and administration of the sulfonamide compounds is much more effective than use of the sulfonamide compounds alone. The principal value of this form of therapy seems to be in the treatment of ocular syphilis. This is understandable when one remembers that the spirochete is susceptible to the higher degrees of fever.

The disadvantages and advantages of the Kettering hypertherm have been given by McGavic.⁷⁵

He observed the following disadvantages: The treatment is a very strenuous one attended by fear, fatigue and some danger of collapse and heat stroke. Constant nursing care is absolutely necessary, one nurse being required for each patient. The machine is rather expensive, and the cost of operation is rather high. The machines are accessible to only a limited number of practicing physicians.

The Kettering hypertherm offers the following advantages: High temperatures are readily attained and maintained when desired and the temperature is easily controlled. No new disease is added, as in malaria therapy. Hospitalization is often not necessary, the patient being treated as an outpatient or at most kept overnight. The action is rapid and the therapy can be given three times a week for acute processes and weekly for the more chronic. Any other treatment, local or general, directed toward ocular or systemic disease may be given concurrently. Antisyphilitic chemotherapy is considered more effective when combined with fever therapy. Typhoid vaccine and other nonspecific proteins can be injected between fever treatments.

More investigation is necessary before definite conclusions can be drawn as to the proper place of air conditioned fever cabinets in artificial hyperpyrexia.

CONCLUSIONS

From a review of the subject of fever therapy in ophthalmology it would appear that certain conclusions are justified.

1. Milk injections are of particular value in the treatment of infants, especially those with ophthalmia neonatorum, since the injections usually cause a fever of 100 to 103 F. This applies even though the sulfonamide compounds are used, as it has been shown that their action is greater in the presence of elevated temperature.

2. Diphtheria antitoxin has many disadvantages, but its use in the treatment of sympathetic ophthalmia seems justified.

3. Typhoid vaccine is the most useful and generally used agent to produce fever for the treatment of acute lesions of the eye and its adnexa. On the theory that vasodilatation may be a factor in the beneficial results, smaller doses administered over a longer period seem as effective and cause less shock and discomfort. The temperature reaction in a series of cases in which

smaller doses were used corresponded closely to that obtained in a series in which the average first dose was 53 million and the average second dose was 80 million organisms. There are certain rather definite contraindications to its use.

4. When a milder fever is indicated or the patient's condition does not warrant typhoid vaccine, the use of Coley's mixed toxins is advisable. This preparation has the advantage that hospitalization is not necessary.

5. Omnadin has a place in the treatment of acute conditions when shock therapy must be avoided but leukocytosis and a rise in the antibody content of the blood are desirable. It is not as effective as typhoid vaccine or other forms of foreign protein but can be used when they are contraindicated.

6. The use of malaria is not justified for ophthalmic diseases.

7. Hyperpyrexia induced by high frequency methods is still in the experimental stage. Further observations are necessary to disclose the conditions in which it is most effective and to establish the dosage compatible with safety.

8. Of the various physical means used to produce hyperpyrexia, air conditioned cabinets of the Kettering hypertherm type are best. Production of fever by physical means is most efficacious in the treatment of gonorrheal conjunctivitis and syphilitic keratitis and iridocyclitis. It is particularly useful in the treatment of syphilitic diseases of the eye. Because of the severity of the treatment it should be used only in those cases in which other forms of therapy are unsatisfactory.

384 Post Street.

ABSTRACT OF DISCUSSION

DR. EVERETT L. GOAR, Houston, Texas: In recent years I have confined my efforts in fever therapy to the use of typhoid antigen given intravenously. I prefer the H antigen because it produces the same therapeutic results as the mixed vaccine, with less discomfort. It seldom causes a chill unless given in a large dose, and the chill is not an essential part of the reaction. The initial dose should vary with the age, size and physical condition of the patient and with the severity of the infection. It is well to start with a small dose—about ten million, unless the infection is a virulent one. Formerly I always hospitalized patients before the initial doses, but with a scarcity of hospital beds I now make an intradermal test and, if this is negative, give them an intravenous injection and let them go home with instructions to keep quiet and to keep a temperature chart. They return in forty-eight hours and the dose is increased. This is the best treatment for anterior uveitis which is not tuberculous or syphilitic in origin. It is much less efficient in posterior uveitis and I am not at all sure of its value in optic neuritis. The only two possible dangers of this type of therapy are (1) anaphylaxis and (2) overdosage or too frequent dosage. Most of the severe reactions are due to the latter. Anaphylaxis may be avoided by preliminary intradermal testing, and untoward reactions may be prevented by small initial doses and by waiting long enough for a secondary rise in temperature to subside before repeating the dose. I have given hundreds of doses to all ages of people, many of them old and in poor physical condition, following these simple methods, and have never seen an alarming reaction.

DR. SANFORD R. GIFFORD, Chicago: In view of the proved efficacy of the sulfonamide drugs in gonococcal infections, the use of foreign protein injections are quite possibly unnecessary in gonococcal conjunctivitis of the newborn. It would be interesting to see a carefully controlled series of patients with gonococcal conjunctivitis treated with sulfathiazole plus fever. Most ophthalmologists will prefer the use of typhoid vaccine for adults or of milk for babies. In acute iridocyclitis the situation is somewhat different. In the absence of syphilis the evidence of a bacterial agent is often wanting, while exact bacteriologic

diagnosis is usually impossible. Most of us at Northwestern University still feel that foreign protein therapy, with or without the sulfonamide drugs, is of considerable value. We employ typhoid vaccine by vein and still find that the dosage of Allen, from 30 to 80 million organisms, usually produces the desired reactions. It is interesting that Dr. Cordes was able to produce such definite reactions with much smaller doses. Fever in our patients is probably, on the average, somewhat higher than in his series, often rising to 103 F. and occasionally to 104 F., but it is by no means certain that the results are superior to his. The preparation of vaccine employed certainly plays a part. The prepared proteins with which fever is not produced would seem to have little to recommend them. In syphilitic iridocyclitis the results of specific therapy are usually so good that it would seem unnecessary to submit these patients to hyperpyrexia. In nonspecific chorioretinitis the case for fever therapy is about the same as in iridocyclitis, except that the results are less dramatic and more difficult to evaluate. The same may be said of fever therapy in optic neuritis and retrobulbar neuritis. Here the evidence for any therapy is vitiated by the tendency to spontaneous recovery in most cases, at least during a first attack. We still employ typhoid vaccine along with large doses of thiamine hydrochloride. Future attacks may be expected in many cases, and the later signs of multiple sclerosis can hardly be prevented by this treatment. In serpent ulcer there still seems to be a place for fever therapy. As Brown has shown, intravenous typhoid vaccine does increase the concentration of antibodies in the aqueous and, presumably in the cornea. With sulfonamide therapy results are undoubtedly better than with fever therapy and local treatment alone. With the use of early keratotomy I have obtained the impression that fever therapy is often unnecessary. Hyperpyrexia by physical means has a definite place in the treatment of those forms of syphilis which are resistant to chemotherapy alone. These are practically limited to interstitial keratitis and optic atrophy. In optic atrophy our experience has been small. In these two exceedingly serious syphilitic conditions it would certainly seem that fever therapy is justified in spite of its admitted inconveniences and expense. The hypertherm would seem, for many reasons, superior to malarial inoculations.

DR. GRADY CLAY, Atlanta, Ga.: My earliest experience was with the use of boiled milk, using it for a child who was admitted to the hospital with a perforated injury to the cornea of a day's duration, and the eye then showed a beginning panophthalmitis. With daily injections of milk the eye promptly cleared. Such a spectacular cure in a heretofore hopeless situation made me an early staunch advocate of such a therapeutic agency. In our clinic at Emory University we have continued to use boiled milk because we have had good results and there is no expense connected with its use. In private practice I now use subcutaneous injections of proteolac and intravenous injections of typhoid vaccine. In every case in which intraocular surgery is done I use the intramuscular injection of foreign protein. I use it routinely in all infected bacterial corneal ulcers, many of the interstitial keratitis cases, and all cases or intraocular inflammations such as iritis, iridocyclitis, uveitis, acute exudative choroiditis and severe types of optic neuritis, especially those associated with encephalitis. I think it best to admit the service patients to the hospital and use intravenous typhoid vaccine as outlined by Dr. Cordes. In using typhoid one should never overlook its dangers, and for that reason it should not be given at the office or at home. The various photographs shown are too numerous to publish but show clearly the different stages of angiospasm, arteriolar sclerosis and the other hypertensive stage discussed in this paper.

DR. FREDERICK C. CORDES, San Francisco: Typhoid H antigen is often regarded as being without danger, owing to the fact that it can be given in the office. Because of this two points brought out by Dr. Goar bear emphasis, namely the possible danger of anaphylaxis and overdosage. He doesn't give his method of doing the intradermal test but I imagine it coincides with that of Brown, who advocates the intradermal injection of 1 minim (0.06 cc.) of a solution of H antigen (25 million organisms per cubic centimeter). If no local reaction takes place within twenty to thirty minutes, he feels that

the patient is not sensitive. I agree with Dr. Gifford that the sulfonamide drugs are so effective in ophthalmia neonatorum that milk injections are probably unnecessary. In the use of fever therapy it is well to remember that a patient who has had typhoid may not react to typhoid vaccine. In such a case seen recently hyperpyrexia by physical means was found useful in helping to control a severe uveitis. I agree with Dr. Clay that typhoid vaccine should not be given at the office or at home because of the possible reactions that may at times be encountered in its use.

PLASTER OF PARIS CASTS

AN EXPERIMENTAL AND CLINICAL ANALYSIS

CAPTAIN J. VERNON LUCK

MEDICAL CORPS, ARMY OF THE UNITED STATES

Wars impel us to improve our technic of applying casts. It was to enable him to use plaster of paris conveniently on the battlefield that led A. Matthysen, a medical officer in the Dutch army, to invent and describe the plaster of paris bandage in 1852. He employed a coarse cotton bandage and manually rubbed plaster of paris into it, very much as we do today. This was a great improvement over the method of mixing the plaster of paris with water and pouring it into a box enclosing an extremity, a method that had been in use for the preceding half century.

In every war since the Crimean (1854-1856), plaster of paris has been extensively used; but in this present conflict there will be more plaster of paris used than in all previous wars combined. For many wounds, encasement in plaster of paris represents the best method of treatment.

During the past 2,500 years, man's search for the ideal cast medium has never ceased. A multitude of materials have been utilized, many of which have been recommended by their creators as superior to plaster of paris. However, nothing now known threatens the position of plaster of paris as the most universally acceptable cast material we possess.

Through the decades of the past 150 years the pendulum of popularity has swung to and away from the use of plaster of paris many times. Critics of its use have had their day only to see plaster encasement again rise as a dominant method of treatment. Numerous errors in the use of this method of treatment have been corrected only to be forgotten and later rediscovered and recorrected.

From the standpoint of the plaster itself, so much has been accomplished by manufacturers that most plaster of paris and crinoline now on the market is consistently good. Far more of the unsatisfactory casts examined were the result of poor technic of application than the result of defective plaster of paris and crinoline. Of course the bandages must be well made; if they are too tightly rolled they soak incompletely and have dry spots; if too loosely rolled they telescope. Since there are comprehensive treatises available on the preparation of plaster bandages,¹ this paper will deal principally with the technic of application. Each detail in the technic of applying plaster of paris casts and splints will be analyzed in terms of its capacity to

weaken or strengthen the cast. Several important points herein advised are based on the results of experiments.

THE SETTING PROCESS

Since an understanding of the setting process and chemistry of plaster of paris is indispensable to good plaster technic, a brief description is in order. Plaster of paris (anhydrous calcium sulfate) is mined from underground deposits where it exists as a solid crystalline material known as gypsum (hydrated calcium sulfate). In its natural state gypsum is mixed with impurities such as silicates, iron and carbonates. To refine gypsum and transform it to plaster of paris, it is heated to around 120 C. to drive off most of the water of crystallization, $2(\text{CaSO}_4 \cdot 2\text{H}_2\text{O}) \rightleftharpoons (\text{CaSO}_4)_2 \cdot \text{H}_2\text{O} + 3\text{H}_2\text{O}$. Removal of nearly 100 per cent of the impurities and the addition of a proper accelerator to reduce the length of the setting time completes the preparation of orthopedic plaster of paris.

When plaster of paris is soaked in water it promptly takes up water and goes back into a solid crystalline state. Viewed microscopically, crystals rapidly form and interlock. It is the tight interlocking of the crystals that gives the plaster much of its ultimate strength. But this important phenomenon will not properly occur unless the plaster is undisturbed during most of the setting process. This can be observed both microscopically and clinically. No single point in the application of plaster of paris is more important or deserves more emphasis than the protection of the plaster from movement during that decisive period when the plaster is going from a fluid to a solid state. In appreciating the need for immobilization during this initial setting period, it is helpful to view the crystallization process microscopically. Figure 1 is a photomicrograph of plaster of paris in powdered form ready for use. In figure 2, water has been added and the crystals have been allowed to form and set undisturbed. Figure 3 indicates the pattern of a field of crystals that were disturbed by a moderate amount of movement during the period when the powder was taking up water of crystallization and consolidating. A comparison of figure 2 and figure 3 reveals two important differences. First, the crystals in figure 2 are closely interlocked, as compared to a loose interlocking in figure 3. Second, the crystals in figure 2 are long and thin, whereas those in figure 3 by comparison are short and thick. For maximum strength in a plaster of paris cast or splint, everything possible must be done to encourage the proper formation and interlocking of the crystals.

It is extremely important that physicians and technicians who apply plaster of paris casts and splints become familiar with what may well be termed the "critical point." The "critical point" may be defined as that point in the setting process when immobility of the plaster becomes imperative if the cast or splint is to set properly and become rigid. Molding the cast, changing the position of a joint or fracture fragment should be carefully avoided subsequent to the "critical point." Recognizing the "critical point" requires experience and varies with different brands of plaster. In general it is reached when the plaster has attained the consistency of thick cream. Once the plaster loses its wet glistening appearance or becomes grainy, the "critical point" is past. When in doubt, errors should be made on the side of safety.

When water is added to plaster of paris powder, the crystals that form are about one-fifth water of crystallization. After the plaster sets, all water in excess of that

From the Orthopedic Service, Station Hospital, Army Air Base, Santa Ana, Calif.

Experiments herein reported were made possible through funds and facilities provided by the Douglas Aircraft Company of Santa Monica, Calif. Engineers from the stress group, Mr. Charles Strang, chief stress engineer, Mr. Louis Abraham and Mr. George Halgedahl did the calculations and assisted in the experiments.

1. McLin, W. C.: Hospital Made Plaster Bandages, *Modern Hosp.* 55: 51 (Aug.) 1940.

required for the crystallization process disappears by evaporating from the surface. In thin casts this may take place in a matter of hours, but in thick casts it is usually a matter of days. The rate with which evaporation occurs depends on the air, its humidity, its tempera-

Fig. 1.—Plaster of paris in powdered form ready for use ($\times 300$).

ture and its circulation around the cast. Casts may appear dry on their surface and contain considerable water in their deeper layers. The experimental casts had to be dried for seven days to assure that virtually free water in them had evaporated. In some of the st tests, casts one or two days old were used and

Fig. 2.—Plaster of paris crystals ($\times 300$) which were not disturbed during the setting process. Note the compact interlocking of the crystals.

when compressed only a few hundred pounds in the Southwark machine they would not crack or break but would simply flow and collapse, and drops of water would appear on the surface. There was a steady increase in strength of the casts for the first three to

six days as more and more of the excessive water came to the surface and evaporated.

It is a mistake to assume that a cast attains its full strength the first day after application. In wet, humid climates a heavy cast may remain weak and wet for many days. Under such circumstances a cast drier and free circulation of air around the cast are indispensable. When evaporation from the surface of a green cast is prevented by heavy blankets or humid air, the cast will frequently become rubbery and useless.

EXPERIMENTAL PLAN AND SETUP

Plaster of paris cylinders were made on three piece wooden forms. Three piece forms were made so that a wedge shaped center section could be drawn out after the cast had set, thus making it easy to withdraw the two lateral parts of the form. It is far simpler to remove a three piece form from a plaster of paris cylinder than it is to remove a form made in one piece. Two types of plaster cylinders were made: one for a compression test setup and the other for beam-test

Fig. 3.—Plaster of paris crystals ($\times 300$) that were disturbed by motion after the "critical point" in the setting process. Note the sparse interlocking of the crystals.

experiments. Compression-test casts were made 12 inches long, beam-test casts 26 inches long, and all casts were 5 inches in diameter. Plaster bandages 4 inches wide and 5 yards long were used, and most of the casts were six layers thick.

Plaster bandages and splints were kept uniform in size and in plaster content. For further uniformity, I made all plaster cylinders. Each cylinder was dried under the same heat and humidity for seven days before testing. All casts were reinforced on the ends to prevent end failures.

The machine employed for testing the load capacity of the plaster cylinders was a Southwark machine of 60,000 pound capacity (fig. 5). The compression test setup is shown in figure 6. To assure uniform compression, ends of casts were sawed square and smooth and each cylinder was placed in the Southwark machine vertically between two firm rubber pads. Except when testing the strength of cast reinforcements, the compression test was considered most indicative of the strength of the plaster-crinoline combination.

In the beam-test setups (fig. 5), the cylinder rests in a wooden cradle which contacts the cylinder only at its ends. A wooden saddle sits on top of the cylinder beneath the compressing head of the Southwark machine. Cradle and saddle contacts with the cylinder were covered with rubber. Two wooden bulkheads 3 inches thick were placed in each end of the cylinder to prevent end failures. It was the area of the cylinder between the saddle ends that was being tested, and, with the type of loading shown, a uniform moment was assured.

For each individual test, two to four identical plaster cylinders were made. Additional cylinders were made later if tests on identical cylinders showed more than a slight variation in strength.

Actual figures representing results of the various tests have only a relative value. They represent results from one particular brand of plaster and crinoline. A few tests were made using different brands of plaster

Fig 4—Ultimate load versus water temperature for constant soaking time.

and all showed similar values. No attempt was made to determine the relative merits of the various brands of plaster of paris now available.

EFFECT ON ULTIMATE STRENGTH OF BENDING THE CAST DURING THE SETTING PROCESS

In this experiment the compression test setup was used and the plaster bandages soaked five seconds in water at 95 F. Two series of cylinders were made, one series for control, which were undisturbed during the setting process, and the other series, in which each cast was bent once during the setting process. The bend was to an angle of approximately 25 degrees, following which the cylinder was immediately straightened and the setting process allowed to proceed to completion. Such a solitary bend was made in the cylinders during various stages of the setting process from the "fluid" to the "solid."

During the fluid stage no reduction in strength resulted from the bend. The casts bent directly after the "critical point" in the setting process showed a

77 per cent reduction in their ultimate strength, as indicated in table 1. During compression of these casts the breaking point invariably appeared at the site in which the cast had been bent. Those casts that were bent after they had become solid never regained rigidity

Fig. 5.—Southwark stress testing machine and the setup used for beam tests.

at the site of the bend and so were not tested. The earlier in the setting process a cast is bent, the less will be the damage to the ultimate strength; the later the bend, the greater the damage.

In analyzing several hundred defective plaster of paris casts that had been used clinically, more were found to have been weakened by having been bent or compressed following the "critical point" in the setting process than by any other single cause. Sources of erratic bendings and compression were as follows:

1. Too slow application of the cast and too rapid setting time of the plaster often lead to movements in the cast long after the "critical point." The setting time of the plaster should be sufficiently long to permit application of the cast before an appreciable degree of setting

Fig. 6—Compression test setup

occurs. A method of varying the setting time without the use of chemicals is to be described later.

2. Fracture fragments and joints should be placed in their proper position and alignment before the cast is applied. A change of position after the cast has been applied is not only a source of wrinkles and pressure

points inside the cast but very often greatly weakens the cast by disrupting the setting process.

3. In the case of body casts and shoulder and hip spicas, do not move the patient too soon after the cast has been applied. A bend or break in the cast often occurs when the patient is moved onto a litter or turned in bed. A bend or break after the cast has become solid may so weaken it as to render it useless.

4. Molding and heavy rubbing, if too prolonged, can greatly weaken a cast and therefore should be avoided except during the fluid stage. Extensive molding is usually made necessary by the use of a thick layer of padding. This padding is more of a liability than an asset to good plaster technic. Only occasionally is more than a thin layer of padding indicated. Plaster bandages should be laid on, not drawn on. When thick padding is used there is a strong tendency to apply the plaster bandage under tension, which is always a dangerous procedure. With thick padding there is increased opportunity for friction to occur between the skin and the cast. Painful points are produced more frequently

by friction in a thickly padded cast than by pressure from casts having little or no padding.

5. During its application, if a plaster bandage becomes stiff or grainy it should be discarded. If stiff, the plaster has set too much to fuse into the cast or the crinoline is defective and failed to soften when soaked. In either instance the bandage should not be used. A stiff bandage, by not adapting itself to body contours, invites pressure points. Grainy plaster is

plaster that has already set and would detract from rather than add to the strength of the cast. A rubbery cast is usually the result of using partially set bandages. Plaster bandages should be applied in rapid succession so that all layers will fuse to form a solid cast. A time interval between bandages invites lamination, one of the most common defects found in plaster casts. Ideally, the entire cast should be completed before any of the plaster in it passes the "critical point" in initial set. If bottom layers set before top layers are applied, application of the top layers may create movements in the bottom layers, thus impairing their strength.

7. Wedges and large windows should not be made in green casts when avoidable. A green cast tends to compress at the site of wedging, and a large window may lead to a bend or break in the remaining circumference.

ULTIMATE STRENGTH OF PLASTER CASTS AS RELATED TO TEMPERATURE OF WATER AND LENGTH OF SOAKING TIME

In treatises on plaster of paris, little has been said of the influence of the temperature of the water and length of soaking time on the strength of the cast. Since varying the temperature of the water has a decided

effect on the length of the setting time of plaster of paris, it was decided to prepare a series of plaster cylinders, graduating the soaking time and the temperature of the soaking water. Twenty-eight sets of cylinders were made, seven sets for each of four temperatures: 40, 70, 95 and 125 F. At each of these four tem-

Fig. 8.—Section at left was from a cylinder made by good technic. The section at the right was from a cylinder that was bent once soon after the "critical" point in the setting process.

peratures a set of cylinders was made for each of the seven different length periods of soaking: five seconds, one minute, two minutes, three minutes, four minutes, five minutes and six minutes. The compression test setup was used. With the five seconds soaking time, little alteration in the strength of the cast occurred

TABLE 1.—An Experimental Indication of the Damaging Effect of Bending a Plaster of Paris Cast Following the "Critical Point" in the Setting Process

Test Number	Soaking Time	Temperature of Water	Average Load (Compression)	Comment
1	5 seconds	95 F.	5,300 pounds	Prepared under optimum conditions
40	5 seconds	95 F.	3,600 pounds	One bend directly after "critical point"

from varying the temperature of the water; but as the period of soaking was increased there was a steady rise in strength of the casts until the soaking time reached four minutes, with the temperature of the water at 95 F. At a soaking time of four minutes or longer and with the temperature of the water above 95 F., cylinders showed a rapid and progressive decline in strength.

Fig. 9.—Section on right from a cylinder made of plaster bandages forcefully wrung out immediately on removal from the water, with a pronounced loss of plaster. Section on left was from a cylinder made of plaster bandages which were properly soaked and drained.

Using water at a temperature of 40 F., there was a progressive increase in strength of the casts as the soaking time was increased (five seconds to six minutes). Cylinders exhibiting the greatest resistance to compression stresses were those made with the water at 70 F. with a soaking time of four minutes.

Plaster that was deposited in the bottom of the bucket after all rolls used for each individual cast had been soaked and removed was saved and weighed. At a soaking time of five seconds the accumulation was as much as 35 per cent of the plaster originally incorporated in the bandages. When the soaking time was progressively increased, the amount of plaster in the bottom of the bucket progressively decreased until at a soaking time of three minutes to six minutes there was only an insignificant amount of plaster lost from the rolls.

Applying a cast to a wooden form is not quite the same as applying a cast to an arm or a leg. In the case of the experimental cylinders they were applied in about three minutes and allowed to set without the slightest disturbance. Since the wooden forms were rigid there was no disturbance of underlying layers as top layers were applied. In tests on the influence of long periods of soaking, the plaster frequently had thickened and setting was near the "critical point" when the bandages were removed from the soaking water. In such instances even a brief delay would have resulted in a defective case, owing to manipulation of the bandages subsequent to the "critical point" in the setting process. In those instances of long periods of soaking in which the cylinders proved to be weak, the plaster had passed the "critical point" at the time it was removed from the water or did so during the application of the bandages.

It is generally agreed that the use of such materials as salt to accelerate the setting time and sugar to retard the setting time is an unwise practice in most hands. Varying the temperature and soaking time is a good method of accelerating or retarding the setting time. At 40 F. the initial setting time was approximately three times as long as it was at 125 F. with a soaking time of three minutes.

In general it may be said that the earlier in the setting process that the cast can be completed and kept quiet until it sets, the greater the ultimate strength of the cast. In applying small casts that can be applied quickly, or if the setting time of the plaster is excessively long, it is permissible to prolong the soaking time until the plaster attains a creamy consistency. Such a practice should not be carried too far in an attempt to retain all of the plaster in the bandages.

When soaking is completed, the bandages should be gently removed from the bucket and allowed to drain for ten or more seconds in another bucket, a perforated receptacle or sink, before gently compressing out remaining excess water. Squeezing the bandage immediately on removal from the water presses out much of the plaster that could have been conserved by proper technic (fig. 9). Since plaster of paris that accumulates in the soaking water accelerates the setting time, it is best to use an abundance of water, drain the rolls outside the bucket in which they are soaked and use a bucket of water for not more than six bandages.

REINFORCEMENT OF PLASTER OF PARIS CASTS

In applying a cast to immobilize a joint moving predominantly in one plane, such as the knee and elbow, there has been a difference of opinion regarding the site for most effectively reinforcing the cast. Opinion is divided as to whether reinforcement is more effective when placed on the anterior and posterior surfaces or when placed laterally and medially. Stress engineers have long known the answer to this question. The answer evolves from a basic principle of mechanical

engineering; in fact, the pattern of construction of the much used I beam is based on this principle.

By calculations (table 2) reinforcements placed front and back in a cast over a joint moving in one plane are much more effective than similar reinforcements placed on the sides. Tests were made to determine whether or not these calculations could be corroborated experimentally. Plaster cylinders were made with rein-

TABLE 2.—Calculations

Referring to the beam test setup (fig. 5), the moment on the center of the cylinder was:

$$\frac{P}{2} \times 8 = 4P \text{ inch pounds.}$$

S = number of inches from each end of cradle to end of saddle.
 P = pounds of force exerted on saddle.

If the maximum allowable unit stress is represented by S and the distance to the outer fiber from the neutral axis is represented by O :

$$S = \frac{MO}{I}$$

M = Moment
 I = Moment of inertia

$$M = 4P = S \times \frac{I}{O}$$

$$P = KI \left(K = \frac{SO}{4} \text{ which is constant} \right)$$

Thus, the larger the value of I , the greater load the cast will sustain. I is the moment of inertia of the cross section of the cylinder and is a function of the placement of the material.

$$I = \sum y^2 dA$$

$$dA = dy \cdot dx$$

This relationship indicates the more remote the concentration of material from the neutral axis, or axis through the center of gravity of the cross section, the greater the load carrying ability of a given cross sectional area of material. This was borne out in the beams tested (table 3).

forcement at top and bottom and others with reinforcement on the sides. Cylinders were also made with all of the reinforcement on one aspect to determine whether it is better to divide the splints between two opposite aspects of the cylinder or concentrate them on one surface. Plaster splints 4 inches in width were used for the reinforcements and were incorporated into the casts their full width, except in one series of cylinders in which the splints were folded longitudinally on themselves to give a splint 2 inches wide with double the number of layers. By calculation, the narrow thick splint offers stronger reinforcement than does a wide thin splint. To complete the beam test group, a series of cylinders was made in which yucca board splints were incorporated into the casts in place of plaster splints.

The experimental results showed that anterior and posterior reinforcements added more strength to the cast than did similar reinforcement on the side, as was indicated by the calculations. There was remarkably little disparity between the calculated strength and the strength determined by experiment. By calculation the splints placed anteriorly and posteriorly should have

produced casts that were 39 per cent stronger. An increase in strength as substantial as this has real practical value.

The results of test 20 (table 3) indicate that it is better to divide the splints between front and back than to place them all on the compression side. A division of the splints was an average of 26 per cent stronger.

Test 23, in which the splints were folded on themselves to produce narrow splints with double the number of layers, revealed a substantial increase in strength, as was also indicated by the calculations. The farther from the neutral axis the reinforcement is concentrated the greater will be the strength imparted to the cast. In the case of a cast applied to immobilize such joints as the knee or elbow, this means the closer to the midline anteriorly and posteriorly the reinforcement is concentrated the better for the cast. Conversely, the closer to the lateral midlines the reinforcement is placed, the less the strength contributed to the cast.

In analyzing cylinders in which wooden splints had been incorporated, a single yucca board splint was found to add more strength to a cast than a plaster splint 4 inches in width and six layers thick. In order to key

TABLE 3.—Average Load, Type of Failure and Figure of Merit with Different Arrangements of Similar Reinforcing Plaster Splints

Test Number	Load in Pounds (Average)	Type of Failure	Comment	Figure of Merit
31	445	Tension	No reinforcement	1.00
26	815	Tension	Three layer splint top and bottom (anterior and posterior)	1.85
24	585	Tension	Three layer splint on each side (lateral and medial)	1.31
20	645	Tension	Six layer splint on compression side (posterior)	1.36
33	760	Tension	Six layer splint 4" wide on compression side, folded longitudinally to 2" width and twelve layers	1.71

nonplaster splints into the casts so that they would not separate from adjacent layers of plaster, it was necessary to make multiple perforations or notches in the splint. This procedure substantially increases the strength of the cast, especially on the tension side.

USE OF PLASTER SPLINTS OR SLABS ALONE

A point must be emphasized regarding the use of plaster splints or slabs alone; that is, without incorporating them into a cast. The principles guiding the use of splints incorporated into casts do not hold when splints are used alone. In fact, the mechanical principles involved are just the opposite in important respects. Splints used alone offer much stronger support when placed on the sides than when placed front and back. Also splints used alone are more effective when broad and thin than when narrow and thick. In applying molded plaster splints anteriorly or posteriorly, it is best to make them broad so that they extend well onto the sides. When feasible, plaster splints should be applied exclusively on the sides. By calculation it is possible for splints placed on the sides to be as much as sixteen times as resistant to bending stresses as similar splints placed anteriorly and posteriorly.

SUMMARY

1. Immobilization by encasement in plaster of paris is an indispensable part of the treatment of many war wounds and demands good plaster technic. Good plas-

ter technic means rapid application of the cast, comfort and protection to the patient, the use of a minimum of plaster, and less difficulty in transportation.

2. Plaster of paris, a powder, transforms to crystals when mixed with water. In the crystalline state it depends principally on compact interlocking of the crystals for its rigidity and strength.

3. The "critical point" is that time in the setting process when the plaster crystals interlock and give the cast rigidity and strength. Movements of the cast, such as changes of alignment and molding after the "critical point" in the setting process, mean impairment of the ultimate strength of the cast. The later after the "critical point" the cast is manipulated, the greater will be the damage. Of the defective casts analyzed, more had been impaired by manipulation after the "critical point" than by any other single cause.

4. Detection of the "critical point" requires practice and varies with different brands of plaster, but in general it is that point when the plaster is of the consistency of thick cream and begins to lose its wet glistening character. When the appearance of the plaster has become dull and the cast is becoming firm, the "critical point" is passed.

5. Lamination of casts occurs when one layer of plaster-crinoline dries before another is applied, preventing fusion of adjacent layers. When fresh plaster is wrapped over a dry plaster surface, the dry surface should first be roughened by scratching it with a sharp knife. This is necessary when casts have to be applied in segments, e. g. a cylinder for a shaft fracture of the tibia and fibula, then the foot portion, then the thigh portion.

6. Most plaster of paris and crinoline now available is good. More unsatisfactory casts are the result of poor technic of application than derive from defective plaster of paris and crinoline. To overcome bad technic of application, a great excess of plaster is frequently used. The use of two or more times the required number of plaster rolls and splints is often observed.

7. A cast does not attain its full strength until the water within it in excess of that needed for "water of crystallization" evaporates. This process may require several hours for small casts and several days for large ones. Arrangement for air to circulate around the cast until it dries is important. If a large wet cast is kept covered with heavy bed clothing, the cast may lose its rigidity and become rubbery and useless. This is especially true in humid climates.

8. The use of such materials as sugar to retard the setting time and salt or borax to accelerate the setting time should be avoided under most circumstances. Cold water effectively retards the setting time and warm or hot water accelerates it. Varying the temperature of the water and the length of the soaking time are usually adequate to regulate the setting time. Water at a temperature of 70 to 95 F. and a soaking time of about one minute are ordinarily employed.

9. In the defective casts analyzed, more painful points resulted from friction beneath thickly padded casts than resulted from pressure when little or no padding was used. When no padding is used a plaster splint is best applied anteriorly and posteriorly before applying the plaster bandages. The bandages should be "laid on," never "drawn on."

10. With reinforcing casts that encase the ankle, knee, elbow and wrist, the reinforcement should be placed front and back and not on the sides. Major reinforcement for the shoulder in shoulder spicas should

be over the top of the shoulder and in the axilla; for hip spicas reinforcement should be placed anteriorly, posteriorly and laterally, with the strongest reinforcement laterally.

11. Splints contribute more to the strength of a cast when they are thick and narrow than when they are thin and wide. Nonplaster splints should be perforated or notched in order to key them into the cast.

12. When plaster splints and slabs are used alone and not incorporated in a cast, the rules for their application are opposite in two respects to their use in casts. In immobilizing joints moving predominantly in one plane, such as the knee and elbow, splints or slabs used alone are stronger when they extend well up on one or both sides or are used exclusively on the sides. Further, they are better used thin and broad, rather than narrow and thick.

SEMIMEMBRANOSUS BURSITIS

ASSOCIATION WITH TEAR OF THE INTERNAL
MENISCUS OF THE KNEE JOINT
BY COMMON TRAUMA

MICHAEL BURMAN, M.D.
NEW YORK

The usual popliteal cyst is the enlarged semimembranosus bursa. This constant bursa is located beneath the deep fascia of the popliteal space in the interval between the semimembranosus muscle and the medial head of the gastrocnemius muscle and is intimately attached to the posterior capsule of the knee joint and its bordering muscles. It may communicate with the knee joint by a small opening. Its anatomy has been well described by Wilson.¹

Semimembranosus bursitis is not common. Wilson reported 21 cases from the Hospital for Special Surgery, and Meyerding and Van Demark² 15 cases from the Mayo Clinic.

Some, as Meyerding and Van Demark, state that enlargement of this bursa is not caused by trauma and is often associated with rheumatoid arthritis or osteoarthritis. Were arthritic association significant, it would be seen more often.

This report shows the clinical association by common trauma of the enlarged semimembranosus bursa and the torn internal meniscus of the knee joint. This association is not recorded in the literature dealing with semimembranosus bursitis. It has significant medico-legal import. I have operated on 3 patients in whom both the semimembranosus bursa and the torn internal meniscus were removed at the same time. A fourth patient was seen in whom a strain of the anteromedial part of the knee with questionable meniscal tear was associated with bursal enlargement. In this case only the bursa was removed.

REPORT OF CASES

The cases are briefly recorded:

CASE 1.—A man aged 38 jumped from the fender of a truck 3 feet to the ground, twisting his right knee inwardly. Since then he had had a limp, pain on the inner side of the knee and a swelling back of the knee. His knee was asymptomatic

1. Wilson, P. D.; Eyre-Brook, A. L., and Francis, J. D.: A Clinical and Anatomic Study of the Semimembranosus Bursa in Relation to Popliteal Cyst, *J. Bone & Joint Surg.* 20: 963 (Oct.) 1938.

2. Meyerding, H. W., and Van Demark, N. E.: Posterior Hernia of the Knee (Baker's Cyst, Popliteal Cyst, Semimembranosus Bursitis, Medial Gastrocnemius Bursitis and Popliteal Bursitis), *J. A. M. A.* 122: 858 (July 24) 1943.

before the accident. He noted the swelling of the popliteal space four days after twisting his knee. The knee joint had not locked.

He walked with a slight right knee limp. Tenderness was present over the medial joint space and over the internal lateral ligament. A tender bursal swelling $1\frac{1}{2}$ inches long and 1 inch wide was seen posteromedially. Motions of the knee were full.

A diagnosis of semimembranosus bursitis and associated strain of the internal lateral ligament with questionable meniscal injury was made. The bursa was excised on June 11, 1943, about five weeks after the date of injury. His convalescence was not eventful.

CASE 2.—A man aged 29 put his right knee out of joint on March 1, 1938 as he squatted to look under his truck. He had immediate pain on the inner side of the knee and could not extend it or bear weight on it. He heard a snap in the knee as it became locked and felt as if something blocked extension. This was the fifth locking, the first occurring on Dec. 2, 1937, when his right foot slipped on a piece of fat as he was lifting a hind of beef. The knee twisted inwardly. A snap was heard and the knee locked for a few minutes, being unlocked by extension. The interim lockings lasted one-half to one hour.

He walked with an obvious right knee limp. Extension was 170 degrees and flexion was full. The joint was stable laterally but there was slight anteroposterior instability by relaxation of the crucial ligaments. Tenderness and swelling were present over the internal joint space, and the abduction-external rotation test gave pain on the inner side of the knee. A small cyst was palpated posteriorly and medially a week after the first examination on March 5, 1943. He did know that he had it.

On March 14 the internal meniscus (bucket handle tear) and the enlarged semimembranosus bursa were removed. The post-operative course was complicated by a tourniquet palsy of the sciatic nerve, for which neurolysis of the nerve was done on May 3, 1938. He made an excellent recovery.

CASE 3.—A man aged 42 fell six steps on March 3, 1942 while carrying a carton of paper weighing 50 pounds. His right knee twisted inwardly and he landed on both hands. He noted a swelling back of the knee soon after injury. The knee was sore and occasionally swollen on its inner side. He stated that the knee snapped out of place at inconstant intervals, something slipping in the inner side of the joint. This locking was transitory and reduced by shaking the knee into place. He had no trouble with the knee before this accident.

The knee was tender over the internal lateral ligament. Extension was full although he had torn the rectus femoris muscle, but flexion was 15 degrees less than full. No effusion was present. A semimembranosus bursa $1\frac{1}{4}$ inches long and 1 inch wide was felt in the posterolateral part of the popliteal space.

He was reexamined about three to four weeks later. He stated that he could not extend his right knee and that something was blocking extension. He heard a snap on the inner side of the joint and also in the back of the knee when he inadvertently placed the knee in an awkward position. The bursal swelling had varied in size, being larger after use of the knee.

The knee extended to 175 degrees and the internal joint space was tender. The bursa was a little smaller.

On May 4, 1942 the bursa and the internal meniscus were removed. The meniscus was not loose or torn but was thickened anteriorly at the site of asbestos or silvery degeneration. The internal fat pad was slightly enlarged.

Sections of the meniscus showed nothing unusual. The cyst was thin walled and multilocular, and in areas degeneration of the cyst wall was seen.

His recovery was good.

CASE 4.—A man aged 42 caught the toe of his right shoe in a floor depression July 9, 1943 so that, as he fell forward, he twisted his right knee. He struck the anterior part of the knee against the floor. The knee could not be extended, and over a period of two to three weeks it caught many times as something slipped on the inner side of the joint. The knee had been painful and swollen.

He walked with a pronounced right knee limp. The knee extended to 170 degrees and flexed to 10 degrees less than full. Tenderness was noted over the internal joint space and over the internal lateral ligament. The semimembranosus bursa was enlarged.

His condition remained unchanged except that the bursa fluctuated in size, being sometimes so small that it was difficult to palpate it. Operation on July 31 showed that the meniscus had been torn longitudinally along its inner border, the meniscal flap causing the repeated catching of the knee. The meniscus was also fragmented in the horizontal plane. There was a small amount of fluid in the joint. The bursa contained a small amount of fluid and did not communicate with the joint. It was not greatly enlarged. The meniscus and bursa were removed.

He is making an uneventful convalescence.

COMMENT

The trauma which tears the internal meniscus may also cause a semimembranosus bursitis. This is a significant association, emphasizing the need to examine the back of the knee in every case of its injury. The enlargement of the bursa may be occult or obvious, and the swelling may fluctuate in size. This may be due to passage of bursal fluid into the joint and vice versa, but it is more likely an expression of secretory and absorptive power of the bursal wall. The bursa may become fibrotic and no longer palpable. This was seen in one patient in whom only the bursa was involved. The two conditions are, however, separate entities though created by similar trauma. The associated injuries noted were strain of the internal lateral ligament in all cases, relaxation of the anterior crucial ligament in one and rupture of the rectus femoris in another. No patient was arthritic, and the trauma was clear and decisive in the production of the resultant injuries.

The significant popliteal cyst is the enlarged semimembranosus bursa, and the confusing patronym of Baker's cyst should be dropped. Trauma plays an important part in its enlargement. While the patients whom I described were all male adults in the prime period of life, I have seen this bursal enlargement in childhood and in older people. Certainly the bursa may be diseased in arthritis, but it is not a common association.

114 East Fifty-Fourth Street.

The First Hospital in America.—The first hospital in America was established by Cortez in the city of Mexico about 1524. The French established hospitals as early as 1639 in Quebec and Montreal in 1644. It is said that a hospital was opened on Manhattan Island in 1663. Many of these hospitals have had an interrupted operation to the present and their descendants have carried on in some sort of way, but hospitals in America did not really begin until the next century. The Pennsylvania Hospital (1751-56), the Philadelphia Dispensary (1786), the New York Dispensary (1791-95) and the New York Hospital (1791) are the first hospitals that can claim consecutive and successful operation from their foundation. The present Bellevue Hospital began as a room for the sick of the Public Workhouse in 1736; it moved to a new building in 1796 and became a real hospital in 1816. In 1869 it established the first city ambulance service in the world. The Massachusetts General Hospital and the MacLean Hospital for the Insane were established in Boston in 1813. There are now 6,807 hospitals in the United States with 853,378 beds and 671,832 patients.—*The Hospital in Modern Society*, edited by Arthur C. Bachmeyer and Gerhard Hartman, New York, Commonwealth Fund, 1943.

Clinical Notes, Suggestions and New Instruments

A TREATMENT OF PILONIDAL CYSTS AND SINUSES A MODIFIED METHOD OF CLOSURE

MAJOR PAUL N. MUTSCHMANN AND LIEUTENANT GEORGE A. MITCHELL
MEDICAL CORPS, ARMY OF THE UNITED STATES

The high incidence of pilonidal cysts and sinuses found in inductees of the United States Army has aroused widespread interest in this condition. In a basic training center new inductees receive vigorous physical training, and this conditioning is prone to irritate preexisting pilonidal cysts and sinuses. In the recent literature there have been numerous descriptions of the treatment of this defect by both primary and partial closure. This brief report does not describe a new operative method but

Fig. 1.—Cyst excised; sutures in place.

is an attempt to contribute to the evidence in favor of partial closure of these wounds.

There is need for a procedure which requires as short a hospital stay as possible and which will result in a firm stable scar. Our duty as Army surgeons is to repair physical defects to the best of our ability and to return the soldier to duty as soon as possible. Numerous primary or partial closure methods have been described by Cohn,¹ MacFee,² Woldenberg³ and Bacon.⁴ Kooistra⁵ has recently reviewed the etiology and symptomatology as well as the treatment of this condition. The type of closure described in the present report varies somewhat from these methods and has given gratifying results.

From the Surgical Service of the Station Hospital, Basic Training Center No. 7, Army Air Forces Training Command, Atlantic City, N. J.

1. Cohn, Isadore J.: *Am. J. Surg.* 60:61 (April) 1943.
2. MacFee, W. F.: *Ann. Surg.* 116:687 (Nov.) 1942.
3. Woldenberg, S. C., and Sharpe, W. S.: *Surg., Gynec. & Obst.* 76:164 (Feb.) 1943.
4. Bacon, Harry: Personal communication to the authors.
5. Kooistra, Henry P.: *Am. J. Surg.* 55:3 (Jan.) 1942.

The first 37 cases at this station hospital were treated by either primary closure or excision with subsequent packing of the open wound, depending on the judgment of the operating surgeon. The primary closure method did not prove satisfactory and its use was discontinued. When the wound was packed open, better results were obtained but required a period of hospitalization of from eight to sixteen weeks. Treatment of the cysts by the use of Carnoy's or other sclerosing solutions was not attempted. The present method of treatment was then adopted and this has been carried out in the last 52 cases with a resulting shorter hospital period and more satisfactory healing of the wound. In this series of 52 cases a previous excision had been done in 4, or 7.6 per cent; previous excision and drainage had been done in 17, or 32.3 per cent.

PRELIMINARY TREATMENT

When a patient is admitted to the hospital, a careful examination is made to determine whether or not infection is present. Infected patients are placed on a schedule of hot sitz baths two or three times daily until all signs of the infection disappear or until fluctuation develops. If an abscess forms, a simple incision and drainage is done and the patient is permitted to return to duty as soon as the acute symptoms have subsided. Approximately two weeks after drainage ceases or all inflammation has subsided, the patient is readmitted for excision of the sinus tracts. It was noted in this series that those patients who were operated on immediately after infection subsided required a longer hospital stay before complete healing occurred.

METHOD OF TREATMENT

A cleansing enema is given the night before the operation and repeated the following morning. Nitrous oxide-oxygen anesthesia is usually employed. The patient is placed on the operating table in the prone position with a pillow under the pelvis and the head and foot of the table depressed. The buttocks are not strapped apart, for it is our impression that this distorts the soft tissues in the area to be excised with exaggera-

Fig. 2—Incision with sutures in place and tied.

tion of the defect after the adhesive tape is removed. We no longer use methylene blue or other dyes to outline the sinuses, but a probe is inserted into the sinuses to determine their direction and depth and to give an estimate of the area to be excised. An elliptic excision is used, and the skin and subcutaneous fat are removed in one block down to the sacrococcygeal fascia. Careful dissection permits one to distinguish the dirty gray appearance of the cyst wall as well as the sinus connected with it. Hemostasis is secured largely by compression, and it is seldom necessary to ligate bleeding vessels. Only occasionally is it found necessary to use a ligature for hemostatic purposes in the inferior angle of the incision. The skin edges or the subcutaneous tissues are not undermined, and the margin of the skin is attached to the sacrococcygeal fascia by interrupted mattress sutures, using number 18 silk suture as shown in the illustration. No attempt is made to approximate the skin in the midline, and every effort is made to avoid all tension, leaving an open area between the skin edges, which may vary from 0.2 to 1 cm. in width. The interrupted sutures are tied over a roll of gauze moistened with azochloramid tincture placed over the incision and covered by a snug dressing reinforced by adhesive tape. The patient is allowed to assume any position in bed that he desires. An attempt is made to prevent bowel movements for a period of four to five days by the use of camphorated tincture of opium. It was found that this is most desirable in the immediate postoperative period in order to avoid contamination of the wound and subsequent delayed healing. The sutures are removed on the sixth to ninth postoperative day and the patient is permitted to be up and about. The wounds are dressed daily either with boric acid powder or, if a defect is present, with scarlet red ointment to encourage epithelization. The patient is placed on graduated exercise beginning on the tenth postoperative day to encourage firm healing of the wound before returning to his vigorous basic training program.

RESULTS

Fifty-two cases have been treated by this method with an average hospital stay of only 22.6 days. This compares most favorably with the previous series of 37 cases in which primary skin closure or excision with packing was done, with an average hospital stay of 68.4 days. By the adoption of the method described, it may be seen that the average hospital stay has been shortened approximately 46 days, which represents a saving of 2,392 days of hospitalization. Unfortunately it is impossible to follow these patients for a suitable period of time, since the men are transferred to other posts as soon as their basic training is completed. Careful follow-up of patients operated on during their stay at the post revealed that only 5 (9 per cent) had to return to the outpatient clinic for dressing. These cases all healed subsequently.

We have found that the method described gives a fair approximation of the skin margins without interference with drainage, and the wound heals almost as rapidly as when closed by primary suture. From a military standpoint it is valuable in that it permits a soldier to return to full duty in a relatively short period of time.

EASY AND ACCURATE METHOD FOR DETERMINATION OF BLOOD SULFONAMIDES FROM ONE DROP OF BLOOD FROM THE FINGER TIP

JOHAN T. PETERS, M.D., NEW ORLEANS
Visiting Professor of Medicine, Louisiana State University

The general practitioner has to know, during the treatment of his patient with sulfonamides, the blood level of this drug, if higher doses are given. In smaller towns, where no help of larger laboratories is available, the physician needs urgently an easy and accurate method for the determination of blood sulfonamides. Nearly each pathologic conference room has been the scene of the result of a fatal intoxication due to uncontrolled use of sulfonamides. For the general practitioner the diazotization method of Bratton and Marshall,¹ which is almost exclusively used in larger laboratories, cannot be recommended. It is for various reasons trustworthy only in hands well trained by daily exercise in examinations of this kind. But even in well trained hands the sources for mistakes are much more numerous than with the method described in this article. This method is based on a discovery of Kuhnau² in 1938. He found

Dr. Edgar Hull, professor of medicine, gave the use of his laboratory, and Mr. C. Adams assisted in working out certain details of the method.
1. Bratton, A. C., and Marshall, E. K., Jr. *J. Biol. Chem.* 128: 537 (May) 1939.
2. Kuhnau, W. W.: *Klin. Wchnschr.* 17: 116 (Jan 22) 1938.

Fig. 3—Cross section of individual suture, tied

tion of the defect after the adhesive tape is removed. We no longer use methylene blue or other dyes to outline the sinuses, but a probe is inserted into the sinuses to determine their direction and depth and to give an estimate of the area to be excised. An elliptic excision is used, and the skin and subcutaneous fat are removed in one block down to the sacrococcygeal fascia. Careful dissection permits one to distinguish

that Ehrlich's paradimethyl-amino-benzaldehyde, the well known reagent for urobilinogen, produced a yellow dye if added to sulfonamides. The dye is a Schiff base (a base containing the radical $-N=CH-$), namely paradimethyl-amino-benzylidene sulfanilamide, if produced by combination with sulfanilamide. This color reaction is certainly not less, perhaps even more sensitive than Bratton and Marshall's ethylenediamine, which replaces at present the previously recommended naphthylamine as coupling reagent for the diazotization. The reason that Bratton and Marshall's method could hold its own in nearly all laboratories against methods which used Ehrlich's reagent is that these methods yielded, according to laboratory directors, not sufficient simplification, compared with the first mentioned method, or they were completely unreliable because of unsuitable simplifications. This last remark is applicable to Fuller's method.³ This method was tried carefully according to the directions. It was found that the commercial tartrazine, with which the test paper has to be colored, may give tints of yellow so different from the yellow color produced by the combination of blood sulfonamides and Ehrlich's reagent that a comparison was impossible. Monto's method⁴ is much better, but it has the disadvantage that it requires an accurate buffer solution of pH 1.4, which makes the method unsuitable for the general practitioner. Churg⁵ showed that alcohol creates a zone around the point of maximum color intensity in which changes in acidity have practically no effect on the intensity of the yellow color. Moreover, alcohol increases the intensity of the yellow color to such an extent that Ehrlich's reagent may detect 1 part of a sulfonamide in 20 million parts of fluid, probably surpassing in this respect all other reagents for sulfonamides. Churg showed in a series of 100 blood sulfonamide examinations that the method with Ehrlich's reagent, accurately performed, gave practically the same results as Bratton and Marshall's ethylenediamine method. It was considered superfluous to repeat these comparisons. The control of the method with Ehrlich's reagent by adding known quantities of sulfonamides to the blood and then determining these quantities is, according to several investigators, impossible. It seems that a small part of the added sulfonamide, varying with different blood specimens, is bound in compound that cannot be detected by the Bratton-Marshall method or by the methods with Ehrlich's reagent. There is no danger that the blood urobilinogen interferes in a degree of practical significance with the result because the color produced by Ehrlich's reagent with urobilinogen is fifty times weaker than that with sulfonamides, according to Churg. Moreover, the quantities of urobilinogen in blood are small compared with the quantities of sulfonamides in blood after the administration of the usual therapeutic doses. Determination of the urine sulfonamides is less reliable because of the presence of oxidation products of sulfonamides.

Bodansky⁶ advises that in practice only the free sulfonamides be determined because only the quantity of the free drug has clinical importance. It takes only a little more time to hydrolyze the conjugated acetyl compound, but it seems better not to determine the conjugated portion, unless requested, because too often confusion results with the two figures to the detriment of the patient. Methods for the separation of the sulfonamides from certain compounds (for instance succinylsulfathiazole) will not be discussed here, because they are described in several handbooks.

Before it was decided to work out a micro method with Ehrlich's reagent, Churg's method was tried, which, compared with its predecessors, has many advantages. The method, using sulfanilamide standards, requires, up to now, according to the description, 1 cc. of blood and has therefore to be considered as a macro method, as are all methods which use more than one drop of blood. According to experience the general practitioner prefers methods which can be performed with one drop of blood. They are less disagreeable for his patients. With Churg's method one has the choice of using either eleven standards made from sulfanilamide, which are to be replaced every

three or four weeks, or standards composed of mixtures of potassium dichromate and potassium chromate, which last much longer. The author undoubtedly felt that the time consuming preparation of not less than eleven standards of sulfonamides was impractical. Certainly this must be admitted for the general practitioner. Experience with the dichromate-chromate standards demonstrates that their colors do not correspond close enough with the colors of sulfonamide plus Ehrlich's reagent to allow accurate readings.^{6a}

In view of these facts an attempt was made to determine whether it would be possible to simplify the existing methods and especially to elaborate a reliable micro method. This purpose is reached in the method described here. Compared with Bratton and Marshall's diazotization method and its important modification, described by Goth, the advantages are obvious. The method requires fewer reagents and the developed color is much more stable, which diminishes the sources of error. The readings often remained constant for two days, provided the tubes were kept in the dark. Beer's law is not applicable on the developed colored substance. However, it is applicable within limits of 0.5 mg. per hundred cubic centimeters if a dilution of the uncolored filtrate is made before the addition of Ehrlich's reagent.

METHOD

Principle.—A fourth of a cubic centimeter of blood is mixed with saponin and trichloroacetic acid. This mixture is filtered, and to the filtrate is added Ehrlich's reagent. A yellow color will appear immediately if a sulfonamide is present in the blood in a quantity of more than 0.5 mg. per hundred cubic centimeters. The yellow color is compared with the colors of four standards.

Reagents.—1. Aqueous solution of 50 mg. of saponin in 100 cc. of distilled water.

2. Twenty per cent aqueous solution of trichloroacetic acid.

3. Two per cent solution of pure Ehrlich's paradimethyl-amino-benzaldehyde in 95 per cent alcohol. It must be stored in a glass stoppered brown bottle. It remains colorless for a long period of time but should be discarded if it becomes yellow. If only a slight yellow color develops in the presence of an acid, the reagent is still satisfactory.

4. A few powders containing accurately weighed 100 mg. portions of sulfanilamide in each. From one of these powders a stock standard solution is made by dissolving it in 100 cc. of distilled water. This solution, placed in an ice box, will keep for several months. In the preparation of the standards a 10 mg. solution of sulfanilamide per hundred cubic centimeters is prepared by diluting 2 cc. of the stock standard to 20 cc. with distilled water. From this 10 mg. per hundred cubic centimeter solution four solutions are prepared:

Seven mg. per hundred cubic centimeters. Add 3 cc. of distilled water to 7 cc. of 10 mg. per hundred cubic centimeter solution.

Five mg. per hundred cubic centimeters. Add 5 cc. of distilled water to 5 cc. of 10 mg. per hundred cubic centimeter solution.

Three mg. per hundred cubic centimeters. Add 7 cc. of distilled water to 3 cc. of 10 mg. per hundred cubic centimeter solution.

One mg. per hundred cubic centimeters. Add 9 cc. of distilled water to 1 cc. of 10 mg. per hundred cubic centimeter solution.

From these four solutions the four standards are prepared as follows: Of each of these solutions 0.25 cc. is placed in each of four tubes. To each tube 4 cc. of the saponin solution and 4 cc. of trichloroacetic acid solution is added. Filtration is necessary only if there is the slightest cloudiness. Into each of four other very clean tubes, having the same diameter as has the "unknown" tube, is transferred 4 cc. of the mixtures and 2 cc. of Ehrlich's reagent. These four tubes are placed in the colorimeter. These standards keep well in an ice box certainly for two weeks.

5. A simple so-called "tube support" for color comparison. It is a piece of wood with seven holes, so that the tube with

5. Churg, Jacob, and Lehr, David: *Am. J. Clin. Path., Tech. Supp.* 6:22 (March) 1942.

6. Bodansky, Meyer: *Am. J. Clin. Path., Tech. Supp.* 4:151 (Nov.) 1940.

6a. These objections hold also in the case of certain equipment put on the market after this article was written.

7. Goth, A.: *J. Lab. & Clin. Med.* 27:827 (March) 1942.

the unknown can be placed between any two standard tubes. A light blue glass is used as a background at the openings in the colorimeter, because some eyes can distinguish slight color differences in yellow-blue better than in yellow. Duboscq types of colorimeters and a photoelectric colorimeter may be used.

Procedure.—Take with an adequate pipet 0.25 cc. of blood from an ear lobe or finger tip. If oxalated venous blood is available for other examinations, one may use this blood. Blow the blood out in a small mortar. Add 4 cc. of saponin solution. Rub with a pestle and wait four minutes (for hemolysis). Add 4 cc. of trichloroacetic acid solution. Rub again with the pestle. Filter through a retentive filter (No. 5 Whatman) of about 6 cm. diameter. Transfer 4 cc. of the filtrate in a very clean tube. Add 2 cc. of Ehrlich's reagent. Put the tube in the colorimeter. Compare with the standards. If the color of the unknown is more intense than the standard of 7 mg. per hundred cubic centimeters take 1 cc. of the filtrate, dilute it four times (by adding 3 cc. of distilled water). Treat this solution just as the undiluted filtrate. The result of the reading is multiplied by 4.

Conversion Factors.—These are factors by which the reading must be multiplied if sulfonamides other than sulfanilamide are used. The conversion factor for sulfathiazole is 1.7 and for sulfadiazine 1.5. For other sulfonamides which survive the crucial clinical tests, one may calculate the conversion factor as follows. Because the solubility in water of the sulfonamides differs widely, it is advisable to make a 5 per cent solution from the new sulfonamide. Up to the present this has been possible with all sulfonamides. For example, in 100 cc. of distilled water at 37.5 C. the solubility of the free drug is 1,370 mg. of sulfanilamide, 92 mg. of sulfathiazole and 11 mg. of sulfadiazine.

Procedure.—Take three tubes. In the first tube put 5 cc. of a 5 mg. per hundred cubic centimeter solution of the new sulfonamide. In the second tube put 3 cc. of the 5 mg. per hundred cubic centimeter solution plus 2 cc. of distilled water. In the third tube put 1 cc. of the 5 mg. per hundred cubic centimeter solution plus 4 cc. of distilled water; 0.25 cc. of each tube is treated just as the blood filtrate. Compare the standards. Example: The color developed by a 3 mg. per hundred cubic centimeter solution of sulfadiazine corresponds with the color of a 2 mg. per hundred cubic centimeter solution of sulfanilamide. Therefore the conversion factor is 1.5.

SUMMARY

For this micro method with Ehrlich's reagent for the determination of sulfonamides in the blood, one drop of blood is sufficient for analysis. It requires less than half the number of standards used with other reliable methods dependent on Ehrlich's reagent. Moreover, it requires only one reagent; that is, two reagents less than are used in Bratton-Marshall's method. The stain which has to be compared with standards changes much more rapidly in Bratton-Marshall's method than in the methods using Ehrlich's reagent. This property makes the latter method much more reliable in less trained hands. The method can be performed easily and accurately by the general practitioner.

2231 Canal Street.

Invention of the Modern Thermometer.—Even before the invention of the modern thermometer, attempts had been made to estimate the temperature of the human body. In the seventeenth century Santorio Santorio had used a bulb filled with air and opening into a tube. The other end of the tube opened under the surface of some water in a vessel. He placed the bulb inside a person's mouth and the air inside expanded as it became warm and issued in bubbles through the water. By counting these bubbles he could gain some idea of the "hotness" of the person in question. This was an extremely rough and ready method, but it was not until almost two hundred years later that the researches of the physicists, notably Helmholtz and Sir William Thomson (Lord Kelvin), improved the thermometer and placed thermometry on a sound basis.—Haagensen, C. D., and Lloyd, Wyndham E. B.: *A Hundred Years of Medicine*, New York, Sheridan House, Inc., 1943.

Special Article

AMERICAN HEALTH RESORTS

ECONOMIC ASPECTS OF HEALTH RESORT THERAPY

A. M. SIMONS

CHICAGO

These special articles on spa therapy and American health resorts were prepared under the direction of the Committee on American Health Resorts. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the committee. These articles may be published later as a Handbook on Health Resorts.

Value is the basic concept in economics. The question arises as to just what are the values of health resort therapy. The definition and treatment of value in the economics of industry and trade differ widely from those in the economics of medicine. In traditional or "classic" economics value is based on "utility," which is defined as follows in an American textbook on economics:¹

The term utility does not connote any ethical worth. Opium has economic utility as well as bread. Vice has economic utility as well as virtue. The test of economic utility is strictly that somebody wants the good. Whether the want be good or bad, it equally reflects the economic utility of the good. Utility is strictly neutral on the moral aspects of want satisfaction.

The medical profession has always had an entirely different idea of value. The Oath of Hippocrates says:

I will follow that method of treatment which, according to my ability and judgment, I consider for the benefit of my patients, and abstain from whatever is deleterious and mischievous. I will give no deadly medicine to any one if asked, nor suggest any such counsel.

To the medical profession, value of any element in medical practice—education, drugs, technic, institutions or organization—depends on its "utility" in preventing, diagnosing or treating disease. Emphasis is laid on what the economist calls "use value" rather than "exchange value." Such things as air, light, water, scenery commonly have very little "exchange value" but much "use value." Lacking the element of scarcity, they cannot be exchanged in the market for money or other "valuable" goods. The economists call them "free goods" and it is significant of health resorts that they depend largely on giving an exchange value to such free goods.

The dual character of health resort management and treatment constantly combines and confuses these two largely contradictory concepts of value. Practically all health resorts (although there are a few outstanding exceptions) involve two factors both of which are undoubtedly of value in the treatment of disease. The recreational "resort" phase must be operated according to the economics and ethics of business; the therapeutic treatment should be ruled by professional ethics and economics. Recreation, amusement, environment, climate, scenery certainly possess real value according to the medical concepts of the word. They do aid in restoring health. Their management, however, is based largely on the classic economic principle that anything is of value for which a monetary demand can be created. Such an economic demand may be based on as faint a

"trace" of actual use value in the medical sense as some of the "traces" of elements in the analyses of mineral waters. It is difficult to adjust these conflicting ideas of value.

The valuation of the mineral waters more nearly conforms to professional standards. Even here there is much confusion with commercial considerations. New complications are introduced when the waters are bottled and their sale becomes a principal source of income. Even where the original water is not "fortified," "condensed" or transformed into a solid "extract" marketed as a powder, as is quite frequently the case, it is difficult to reconcile the conflicting ideas of value and the resulting marketing practice. Spa publicity often assumes that tradition creates therapeutic value or that value is increased by the antiquity of use, for example during Greek and Roman civilization. The publicity for American spas frequently refers to Indian patronage or to visits by Spanish explorers and early settlers. Tradition is further strengthened by reference to patrons belonging to the class that fixes fashion and social mores. The publicity of an American watering place points with pride to its long patronage by the "élite of society."

Such traditions and social sanctions help to give exchange value to otherwise "free goods"—such as climate, scenery and even the mineral waters—when access to these things is restricted. This exchange value must be large to provide and support the expensive equipment required. Hotels must be built, transportation improved, amusement devices constructed and maintained, and these can be operated with financial success only if a demand is created to support the conduct of such equipment. To create such an economic demand from the fraction of the population living sufficiently high incomes to patronize such resorts calls for a large investment, which in turn requires extensive publicity, expensive advertising and efficient solicitation. This selling effort must be directed not only to a restricted income class but, if the health restoring element is to be stressed, to the fraction of this class who are in need, or at least can be convinced that they are in need, of the health restorative facilities of the resort.

The size of the investment and the annual income necessary to sustain that investment is indicated by the fact that nine of the oldest and most highly developed spas in the United States "represent capital investments of approximately \$20,000,000."² The same authority reports that "the average expenditure per person, the estimate being based on inquiry at the spas themselves, was \$350, the total being \$157,500,000." In some European nations the financial developments and publicity necessary for the maintenance of spas have called into existence extensive organizations involving not only the direct management of the spas but transportation lines and government. There have been several proposals for the formation of some such organization in the United States. A report of the Saratoga Springs Commission to the New York legislature says, concerning investments and publicity:

The state has an investment at Saratoga in land, buildings and equipment of approximately \$8,800,000; \$5,600,000 paid for by the state appropriation and \$3,200,000 by the R. F. C. loan. Only a minority of the people are now getting the benefit of the baths and the waters, because there has not been enough money to tell the public in general of the Saratoga Spa.

In a non-revenue producing department savings may be accomplished by the reduction of expense, but where the expenditure of money is required for commercial development, as in the present case, true economy is the expenditure of sufficient moneys for advertising and promotion to produce a profit upon the moneys already spent.

The medical and professional phase of spa operation is closely involved at every point with this business side. Treatment seems to be largely devoted to convalescent and chronic cases. Since there is a decided lack of institutions for the care of the chronic sick and convalescents in this country, the spas may be looked on as filling this very important deficiency.³

There is an economic obstacle to adequate fulfilment of this role by spas. The overwhelming majority of chronic and convalescent patients are not in the income classes from which the majority of present spa patrons come. There are some provisions for the indigent and low income classes at Hot Springs, Ark., and Saratoga Springs, N. Y., but the economic organization of most spas cannot cater to such classes without outside subsidies and important changes in present types of operation.

European spas have made extensive arrangements to cooperate with insurance institutions and to some extent with relief organizations in providing treatment for persons chronically ill and for convalescents among the low income classes. Special arrangements are provided for the care of indigent patients in the bond purchase "contract" signed as a basis of a loan by the Reconstruction Finance Corporation to the Saratoga Springs Authority.

An ever present conflict centers around the question of where the line shall be drawn between the entertainment and medical aspects of a spa. As far as diet, exercise, entertainment, climate and general environment constitute elements in the treatment of disease, medical supervision would seem to be an essential part of the business side of the spa operation. Where the waters and baths are of real therapeutic value it seems to be generally agreed that they should be prescribed by physicians and administered under medical supervision. This supervision cannot be medically effective unless it concerns itself with many of the economic phases of spa management. Although the financial necessity of more extensive publicity than is approved by the medical profession concerning other methods of treatment may be recognized, its quality and general character should conform to the standards fixed for drugs, hospitals and therapeutic appliances.

The Principles of Ethics of the American Medical Association recognizes the distinction drawn. The sentence which declares that "solicitation of patients by physicians as individuals, or collectively in groups by whatsoever name these be called, or by institutions or organizations, whether by circulars or advertisements, or by personal communications is unprofessional" is immediately followed by the statement "This does not prohibit ethical institutions from a legitimate advertisement of location, physical surroundings and special class—if any—of patients accommodated."

This intermingling, and to some extent conflicting, combination of business and medical management undoubtedly makes efficiency in operation more diffi-

2. Report of the Saratoga Springs Commission to the Legislature, p. 51, Albany, J. B. Lyon Company, Printers, 1930.

3. For discussions of the extent of chronic disease and lack of facilities for the care see Boas, Ernst C.: A Community Program for the Care of the Chronic Sick, *Hospitals* 10: 18 (Feb.) 1936. Goldwater, S. S.: The Hospitalization of the Chronically Ill, Welfare Council, New York, 1935; Institutional Care of the Chronically Ill, American Public Welfare Association, Chicago, 1940. Potter, Ellen C.: Care of Chronically Ill in New Jersey, *J. M. Soc. New Jersey* 38: 27 (Jan.) 1941.

cult. This may be one of the reasons why spas seem to have an even more unstable existence than ordinary commercial undertakings. Replies to the questionnaire of the Committee on American Health Resorts brought information of a large percentage of resorts that had been closed, presumably because of financial failure, and many more that did not reply or from which mail was returned because addressees could not be located. Their prosperity seems to depend on a number of fortuitous conditions. They appear to be very sensitive to economic cycles. Catering to the higher income class makes spa treatment largely a luxury and makes the demand for their services what the economist calls highly "elastic." A small change in such a demand within the comparatively narrow range of possible patrons may cause a wide fluctuation in the percentage of services purchased.

Some further observations of the Saratoga Springs Commission apply to this conclusion:

The fiscal year 1938-39 at the State Reservation at Saratoga Springs has very definitely reflected business conditions throughout the country. There was a decline in income from the bath houses from \$189,370.50 in the previous year to \$167,188.85 during the current year. The unusual circumstance associated with this decrease is the fact that it was caused almost entirely by a reduction in the percentage of higher priced treatments given. In the year just ended such extra and higher cost treatments were almost entirely neglected and a greater demand brought out for the plain mineral water baths at lower prices. Thus, the average income per treatment fell from \$1.39 in 1937-38 to \$1.23 in 1938-39. In addition, the number of charity treatments given increased to 24,971, which represented more than 18 per cent of the whole number of treatments. In 1937-38 the 19,482 charity treatments given were 14 per cent of the whole number.

The financial uncertainty is aggravated by the seasonal character of most spas. Many are open for less than half the year and nearly all show pronounced peaks and depressions in a chart of their annual patronage. This, in part, is due to the combination of recreational and medical features. Patronage of the recreational features is naturally higher during the "vacation" months of the year. Many spas owe much of their attraction to climatic conditions which are dependent on the seasons. Treatment of chronic disease is often "optional" and will be postponed to the most convenient and pleasant time.

All of these conditions being subject to wide fluctuations, it is not surprising that their combined effect renders spa operation financially hazardous. Manifestly continuous operation requires a sufficiently high income during profitable operation to offset the losses in the dull periods. Overhead and depreciation increase with wide variation of employment. High labor turnover and sharply fluctuating wages added to the periodic cost of assembling, training and organizing the labor force, which is greater than in a plant with unbroken operation, increase financial instability.

Many of the economic aspects of spa management are closely related to the type of ownership of the sources of the mineral water and the adjacent land. In the United States, with some notable exceptions, mineral springs have been subject to appropriation with their ownership vested in the possessor of the land on which the springs are located. Some economists have defined ownership as "the right to control the actions of others with regard to the object owned." In the cases of mineral springs such ownership would mean the right to control access to the springs and to the use of the water. The exercise of this ownership over the limited

quantity of the water creates the scarcity on which exchange value can be established.

Ownership by government does not seem greatly to affect the character of the publicity used. The financial "guides" and other promotional literature issued by the spas in Germany, France, Great Britain and the Soviet Union reveal the same type of flamboyant adjectives and exaggeration of the climatic, scenic and recreational activities as is found in the advertising of most American spas. All types of such publicity seem to have the same tendency to exploit spa features as panaceas in terms long made familiar by the distributors of nostrums.

Uncertainty as to the specific therapeutic values of not only the waters but still more of the climatic, scenic and recreational features of spas encourages, rather than restricts, exaggeration in advertising their real or supposed healing power. Remedies for this condition are beginning to be applied in the fields of business and medicine. They consist in the establishment and enforcement of standards of value through research and testing. There are undoubtedly great difficulties in the application of these remedies to the values in spa treatment, although these difficulties are not necessarily insurmountable.

There is a growing tendency in this country to extend the sanitary supervision of spas by health departments. This supervision is, however, little different from that exercised over hotels, restaurants, tourist camps, resorts and other institutions the activities of which may directly or indirectly affect the public health.

There are tendencies and trends even now beginning to take shape that indicate the next steps in meeting some of the economic and medical problems of spa management. Steps have already been taken toward the formation of a national association of spas. Most commercial and industrial lines of business have already formed such trade associations and in so doing have followed the pattern of professional associations in adopting some sort of code of ethics governing their relations with one another and the public. Since the business phases of spa management are so closely intertwined with the practice of medicine, it is certain that any such code formed by an association of spas will need to be brought into harmony with the principles of ethics of the medical profession.

SATURDAY, JANUARY 1, 1944

DEATHS OF PHYSICIANS IN 1943

The obituaries of 3,156 physicians were published in *THE JOURNAL* during 1943. The group included 93 women. The American Medical Directory Report Service, including the United States, possessions and Canada, recorded 3,582 deaths. Of this total 189 were Canadians, a group omitted this year from the regular obituary columns. Deducting the Canadians, a total of 237 deaths more is shown in the Report Service than were included in the published notices in *THE JOURNAL*.

The introduction of the accelerated program for medical students during 1942 precludes an attempt at this time to estimate accurately the net increase to the profession. An increase, however, can be assumed. As of August 14 the graduation of 5,223 students had been recorded. The expected annual average total of students to graduate under the three year accelerated program is 7,000, the heaviest total falling in 1943, when two graduations a year launched the program. On Jan. 1, 1944 the estimated physician population of the United States, exclusive of possessions and temporary foreign, was 188,159.

Age.—The average age at death was 65.2 in 1943, as compared with 65.0 in 1942 for 3,211 deaths published in *THE JOURNAL*. Thirty-nine physicians died between the ages of 25 and 29, 49 between 30 and 34, 71 between 35 and 39, 93 between 40 and 44, 126 between 45 and 49, 158 between 50 and 54, 270 between 55 and 59, 396 between 60 and 64, 545 between 65 and 69, 543 between 70 and 74, 371 between 75 and 79, 265 between 80 and 84, 173 between 85 and 89, 46 between 90 and 94, 9 between 95 and 99 and 2 of 100 or over.

Causes.—Heart disease continues to lead the causes of death among physicians. As is customary, when a contributory factor was returned with a primary cause, both conditions were recorded. Coronary thrombosis and occlusion accounted for 598 deaths, of which 218 occurred in the age group 60 to 69. Angina pectoris and other coronary diseases totaled 136, chronic heart valvular disease and rheumatic heart disease 35, sub-

acute bacterial endocarditis (except rheumatic fever) 11, diseases of the myocardium and pericardium 213, and other diseases of the heart 401. Cerebral hemorrhage, thrombosis and embolism were responsible for 397 deaths, arteriosclerosis 200 and cardiovascular diseases 60. Cancer and tumors in various forms accounted for 323 deaths, 129 falling under cancer of the gastrointestinal tract. Chronic nephritis and uremia totaled 136 and acute nephritis 12. Two hundred and eighteen deaths were attributed to pneumonia, of which 6 were virus pneumonia. In the general disease classification, diseases of the circulatory system contributed to 90 deaths, diabetes 46, postoperative complications 38, other diseases of the gastrointestinal tract 36, tuberculosis 33, diseases of the prostate 32, Hodgkin's disease and leukemia 30, diseases of the nervous system 30, cirrhosis of the liver 26, other diseases of the respiratory system 25, pulmonary embolism and thrombosis 21, other diseases of the genitourinary tract 13, peptic ulcer 13, diseases of the gallbladder 12, asthma 12, other diseases of the liver 11, bacteremia, septicemia and pyemia 11, meningitis 11, pernicious anemia 10, peritonitis 9, other diseases of the blood 7, influenza 7, diseases of the brain 7, appendicitis 6, other diseases of the spinal cord 6, abscess 5, chronic arthritis 4, hernia 3, alcoholism 3, encephalitis 3, diseases of the thyroid 2, bronchitis and pleurisy 2, diseases of the bones 2 and other infectious diseases, acute articular rheumatism and Addison's disease 1 each. Senility was reported in 41 deaths, and 6 were classified as ill defined. There were 45 deaths for which no causes were returned. One death each was reported for epidemic hepatitis, glioma of the brain, gout, massive intracerebral hemorrhage due to rupture of an unidentified vessel, amebic dysentery, chronic undulant fever, agranulocytosis, pellagra, drug addiction, acute circulatory collapse following spinal anesthesia, typhus, acromegaly and myasthenia gravis.

Accidental Deaths.—Of 117 accidental deaths, automobile accidents accounted for 41. Falls were involved in 33 deaths, airplane accidents 22, trains 6, burns 6, bullet wounds 4, drowning 2, asphyxiation 1 and drugs 1. Fractures, which were also included under falls, were of the skull, hip and femur, 13 being recorded for the hip alone. There was 1 unexplained fracture. Of the unusual accidents which have been entered under a general classification, 1 physician was killed in a fall from a horse, 1 tripped over a rifle when hunting, 1 died of a skull fracture received during the Detroit race riot and 3 from burns received when they fell asleep while smoking.

Suicides and Homicides.—Forty suicides were recorded. Bullet wounds led in the method selected with 16, poison 7, drugs 5, cut arteries 4, carbon monoxide 2, drowning 2, hanging 2 and illuminating gas 1. One suicide was unexplained. Shooting was the method in the 4 homicides in the civilian group of physicians.

Miscellaneous Positions.—Among the decedents were 253 who had been teachers in medical schools, 150 of whom had reached the professorial rank; there were 5 deans, 1 associate dean, 1 president of a university and 1 teacher in a public school. One hundred and ninety-one had been health officers, 127 members of boards of health, 116 members of boards of education, 66 coroners, 65 mayors, 63 pharmacists, 45 authors, 35 bank presidents, 33 legislators, 24 members of city councils, 20 editors, 11 members of police departments, 9 clergymen, 9 postmasters, 8 missionaries, 8 lawyers, 6 dentists, 3 members of fire departments, 3 judges, 2 justices of the peace, 2 village presidents, and 1 each had been governor, intern, sheriff and alderman. One had been a member of the Austrian army, 1 chief medical officer of the Supreme Bench of Baltimore, 1 vice consul of Argentina, 1 U. S. minister to Liberia, and 1 a commercial flight surgeon.

Of the total of 3,156 physicians, 558 had served in World War I, 62 in the Spanish American War, 7 in the Civil War and 2 each in the Boxer Rebellion (China), the Boer War and the Philippine Insurrection. Thirty-two were members of the U. S. Public Health Service, 26 of the U. S. Army and 17 each of the Navy, Veterans Administration and Indian Service. Four were in the Air Corps. Twenty-seven were classified in the Army Medical Reserve Corps and 57 not on active duty, 21 were listed in the Navy Medical Reserve Corps, 2 not on active duty. Ten were in the Public Health Service Reserve. Fifty-two were classified in the medical corps of the Army of the United States, 11 not on active duty. Thirty-four were reported in the National Guard; 2 Navy men were assigned to the Marine Corps. Thirty-nine had been members of draft boards in World War I and 84 in World War II.

Association Officers.—Among the decedents 1 had been President of the American Medical Association, 3 Vice Presidents, 1 Trustee, 1 member of a council, 1 chairman of a council, 11 section officers, 1 member of the Judicial Council, 2 committee members and 38 members of the House of Delegates. In state medical societies, 45 had been president, 1 president-elect and two secretaries. Two hundred and fifty had been presidents of county medical societies.

Military Service.—Twenty physicians died in action in World War II and 105 while in military service. One, aged 26, who died in the unexplained explosion of the *Escanaba*, was classified as "killed while in military service." One, aged 29, serving with the medical corps of the Royal Army, died in action while serving in the front line during the advance in Egypt. Five died in the Pacific, 9 in the Solomon Islands, including 4 in Guadalcanal, 4 in the North African area, 1 in Sicily and 1 in a torpedoing off the coast of Cape May, N. J. Of 2 merchant marine casualties, both died in torpedoings, 1 in the North Atlantic and 1 off Iceland. Of those killed in action, 8 were between the ages of

25 and 29, 6 between 32 and 34, 1 between 35 and 39, 2 between 40 and 44, 1 between 50 and 54, 1 between 55 and 59, and 1 in the age group 60 to 64. Of those who were classified under military service, 21 died between the ages of 25 and 29, 18 between 30 and 34, 25 between 35 and 39, 15 between 40 and 44, 10 between 45 and 49, 4 between 50 and 54, 6 between 55 and 59, 5 between 60 and 64 and 1 between 65 and 69. Of the deaths in military service, 12 were attributed to coronary thrombosis or occlusion, 7 to heart disease, 1 to cerebral embolism, 5 to bullet wounds, which are also included in 6 recorded suicides, 24 to airplane accidents, 2 to burns, 4 to automobile accidents, 1 to virus pneumonia, 2 to encephalitis, 7 to some form of pneumonia, 1 to alcoholism, 1 in a bomber crash, 2 to homicide, 1 to drowning, 2 to brain tumor, 3 to meningitis, 1 to carcinoma of the brain, 4 to other types of cancer, 2 to malaria and 1 to bacterial endocarditis. The rest were classified under various physical conditions. In 1942 the obituaries of 11 physicians who died in action were published in *THE JOURNAL* and 37 of those who died while in military service. Thus, *THE JOURNAL* notices record 31 physicians who died in action during the two year period 1942-1943 and 142 who died while in military service. *THE JOURNAL* does not believe that the analysis of the military deaths reflects a true picture of the situation as a whole and believes that the group represents a small percentage of those recorded in Washington but not yet released for publication.

The total of 3,156 physicians includes 1 who died in Missouri but who had been a missionary in the Belgian Congo, 1 in Alaska, 1 in Switzerland, 1 in Edmonton, Canada, and 1 in Newfoundland. An editorial entitled "When and How Physicians Die," published in 1903, was the first review of deaths of physicians by *THE JOURNAL*. A total of 1,400 physicians gave a mean average age of death of 58.

ACETYLCHOLINE AND TRANSMISSION OF NERVE IMPULSES

From the work of Loewi, Dale and Cannon it has been generally accepted that liberation of acetylcholine is concerned in the transmission of nerve impulses across peripheral synapses and motor nerve endings. Hence it became essential to study the chemical reactions involved in the synthesis and breakdown of acetylcholine and to measure the rate of these processes in relation to the speed of the electric potential changes accompanying nerve impulses. This demonstration is a practical impossibility in ordinary nerves, which are too small for chemical studies of this nature. The use by Nachmansohn and his group of the large electric organs of certain fishes which are an accumulation of end-plates permitted the study of acetylcholine metabolism and a more accurate analysis of its relation to transmission of the nerve impulses.

This work has now provided evidence that the metabolic mechanisms like those responsible in the muscle for the mechanical energy of contraction act in nerve tissue in the synthesis of acetylcholine and thus provide electric energy of excitation. An enzyme, choline acetylase, necessary for the synthesis of acetylcholine, was extracted by Nachmansohn and Machado¹ from the electric organs and from rat's brain. According to Nachmansohn and his associates² this enzyme requires for its function the presence of adenosine triphosphate, which supplies energy rich phosphate bonds for the metabolic reactions involved in the formation of acetylcholine. As in muscle, adenosine triphosphate is immediately restored by the breakdown of phosphocreatine, which functions as a reservoir of energy. The rephosphorylation of phosphocreatine is then carried on through the oxidation of dextrose or pyruvic acid. An "acetylcholine cycle" was thus envisaged in which the energy necessary for acetylcholine synthesis is probably given by a chain of reactions similar to that elicited in the muscle during breakdown of carbohydrate.

The liberated acetylcholine is quickly controlled by an enzyme, cholinesterase, present everywhere in nervous tissue. Nachmansohn and his associates³ found in the electric organs a striking parallelism between the electric discharge in volts per centimeter and the concentration of cholinesterase. The amount of cholinesterase present was sufficient to hydrolyze several milligrams of acetylcholine in a period of a few milliseconds, in agreement with the hypothesis that acetylcholine liberation might be intimately connected with the rapid transmission of impulses across synapses and nerve endings. Also the energy provided by the breakdown of phosphocreatine and hence for the resynthesis of acetylcholine was shown by Nachmansohn and his associates² to be sufficiently high to account for the electric energy released by the discharges, or impulses, in the electric organs. This parallelism of concentration of cholinesterase or rate of acetylcholine breakdown, and the caloric energy used in the acetylcholine resynthesis, with the electromotive force released during nerve activity, makes it likely that the metabolism of acetylcholine is the determining factor in the propagation of nerve impulses. As the action potentials of the nerve are surface phenomena, the finding of an increased concentration of cholinesterase in the nerve sheaths⁴ and in the nerve endings⁵ points again to a direct link between the generation

of electric potential changes during nerve activity and the hydrolysis of acetylcholine.

There is much evidence that the concentration of cholinesterase is closely related to the neuronal surface area and that the liberation of acetylcholine occurs throughout the nerve pathways, in peripheral or central neurons⁶ in preganglionic or postganglionic fibers⁷ being only quantitatively higher in ganglions, synapses and end-plates in which there is an extensive endarborization of the nerve fibers and consequent increase in neuronal surface. It is, therefore, probable that the same mechanism, acetylcholine liberation, is responsible for the transmission phenomena not only across synapses and neuromuscular plates but along all nerve pathways.

EXPERIMENTAL DIABETES

Attention has been called in these columns¹ to the work by Dunn, Sheehan and McLetchie² on the action of alloxan on the islets of Langerhans in rabbits and rats. The action in rabbits they describe in some detail. They reported that a single intravenous injection of 300 mg. per kilogram would cause a selective and massive necrosis of the islets accompanied by grave disturbances of the sugar metabolism. They also stated that "so far we can say nothing about the possibility of maintaining animals alive after necrosis of the islands, nor have we obtained chronic lesions by any form of prolonged treatment." In the meantime advances of great interest to the study of experimental diabetes by means of alloxan have been recorded.

Brunschwig and his associates,³ who confirmed the results described with respect to rabbits, found that, in the dogs which survived the intravenous injection of alloxan, hyperglycemia was followed by hypoglycemia and then a pronounced hyperglycemia, which was "sustained for two to three weeks." The islet injury in dogs was not as pronounced as in rabbits. In 3 patients with carcinomatosis they injected 220, 400 and 950 mg. per kilogram respectively of alloxan without any subjective disturbances or effect on the sugar or the nonprotein nitrogen level in the blood. In a preliminary report the Baileys⁴ of the Joslin Clinic and the pathologic laboratory of the Harvard Medical School, Boston, confirm the hypoglycemic action of alloxan observed by Jacobs⁵ and by Dunn, Sheehan

and McLetchie² in rabbits; also the necrotic changes in the islets described by the latter investigators. The Baileys found that the hypoglycemia, "if counteracted by repeated injections of dextrose, is followed by the development of symptoms seen in human diabetes, mainly hyperglycemia, glycosuria, polydipsia, polyuria, acetonuria and lipemia." The response to insulin was prompt.

Dunn and McLetchie⁶ report the production of experimental alloxan diabetes in the white rat. Here again a single subcutaneous injection of 300 mg. of alloxan per kilogram caused necrosis of islet cells, with an initial fall in the blood sugar giving way to a pronounced rise. A continuous diabetes was produced in rats by repeated subcutaneous injections of smaller quantities of alloxan; in other words, diabetes can be produced in rats at will by the selective action of alloxan on the islets. The main purpose of this review is to emphasize the importance of these new methods for the experimental study of diabetes mellitus and carbohydrate metabolism.

Current Comment

POSTWAR GRADUATE MEDICAL EDUCATION

Great concern is frequently expressed about the provision of graduate training for thousands of medical officers who will seek such education after the war. Those whose hospital training did not extend beyond the internship will be especially concerned in this need. The responsibility of medical organizations in this matter is larger than the mere provision of the advanced training which returning physicians desire and deserve. Wartime curtailment of training in many fields of learning will leave our nation poorer in human brains and skills and available expert services, entirely apart from casualties. An uncompensated wartime loss of advanced hospital training for thousands of young doctors would reflect itself in a reduced quality of medical care for years after the war. The responsibility here is clearly an obligation not only to the young doctors but to the health and welfare of the nation. The Council on Medical Education and Hospitals has been at work for several months collecting information on postwar educational facilities. It presents a preliminary report elsewhere in this issue. The results to date are heartening; they give promise that the Council will be able at the close of the war to provide a complete printed list of all available educational opportunities. That these will be ample for the needs of returning medical officers is indicated from the present information, provided plans already begun in hundreds of institutions are continued and extended. All institutions are urged to continue their excellent cooperation with the Council in its further studies of this problem.

AMERICAN MEDICAL DIRECTORY OUT OF PRINT

The extra demand by government agencies and the armed forces has exhausted the supply of the Seventeenth (1942) Edition of the American Medical Directory. An effort is being made to buy back copies of this edition from owners who can spare them. Orders for such copies as can be secured will be filled in the order in which they are received. A Directory will not be published in 1944; possibly the next edition will not be issued until after the war. However, the Trustees will again report the status of the Directory at the meeting of the House of Delegates to be held in June 1944.

FIFTIETH ANNIVERSARY OF JOHNS HOPKINS UNIVERSITY SCHOOL OF MEDICINE

As a testimony to the fiftieth anniversary of the Johns Hopkins University School of Medicine, which opened its doors Oct. 2, 1893, a special bulletin has been published for distribution to friends of the school and to its graduates. The needs of the war effort make impossible a more elaborate celebration of this important event. The bulletin contains a story of the origin of the school of medicine and excellent portraits of those who have held professorships in many departments. One statement deals with the contributions of the school to the war effort. Finally there is a proposal for future development. The distinguished service of the Johns Hopkins University School of Medicine is so widely known by the achievements of its staff and its graduates that there remains only to congratulate all of those who have participated in its progress on having reached a golden anniversary.

VITAMIN B₁ CONTENT OF DEHYDRATED FOODS

A rapid decrease in the thiamine content of stored dehydrated meats and eggs has been reported by numerous investigators. Rice¹ noted that storage deterioration does not take place in a pet food consisting of two parts of meat or meat by-products and one part of a mixture of cracked wheat, ground barley, soya flour, bonemeal, dried skim milk and tomato paste. This suggested the presence of some unknown thiamine stabilizing chemical factor in the cereal-milk-bone mixture. To test this deduction, Rice prepared and stored two samples of dehydrated pork (6 per cent moisture), one sample containing 33 per cent of the cereal-milk-bone mixture, the other being without cereal supplement. After a week of routine warehouse storage (temperature 120 F.) the thiamine content of the unmixed dehydrated pork was reduced to 15 per cent of its original titer, while 74 per cent of the original thiamine titer was still retained in the pork-cereal mixture. Whether or not this retention was due to a vitamin stabilizing chemical factor in the mixed cereals or to physical properties has not yet been determined.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeons General of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession.

POSTWAR GRADUATE MEDICAL EDUCATION

A Preliminary Report by the Council on Medical Education and Hospitals

Thousands of physicians whose hospital training has been interrupted by the call to military service will be seeking advanced training after the war. Therefore the Council on Medical Education and Hospitals has undertaken a study of postwar graduate educational

facilities as one of its major responsibilities. A preliminary survey has been instituted to determine all available and potential facilities for advanced training in connection with intern and residency hospitals, undergraduate and graduate medical schools, departments of health, state medical associations and other

agencies interested in graduate or postgraduate medical education.

Information regarding postwar residencies and fellowships, basic medical science instruction, public health education and other postgraduate courses was requested from 1,267 institutions and agencies including 1,041 hospitals approved for intern and residency training. Replies have now been received from 641 hospitals, 55 medical schools, 25 departments of health, 23 state medical associations and 15 special societies and examining boards. The information obtained is most encouraging. It indicates clearly that constructive planning is under way and that institutions are anxious to cooperate to the full limit of their facilities. The Council recognizes that there will be opportunities for the development of additional high grade training programs in institutions that have not yet reached their full educational capacity. However, it does not wish to encourage the organization of new residencies, fellowships and postgraduate courses unless satisfactory facilities can be provided. While the survey is still incomplete, the following observations are of interest.

RESIDENCIES AND FELLOWSHIPS

How many residencies will be required to meet the demands of medical officers seeking advanced training after the war? There are many unknown quantities as regards the duration of hostilities, casualties among medical personnel, rate of demobilization, opportunities for permanent assignment in the Army and Navy, postwar subsidies and other economic factors. It has been estimated, however, that approximately 12,000 graduates of recent years are now serving in the armed forces whose previous training in civilian hospitals did not extend beyond the intern year. Perhaps 6,000 of this group will later seek hospital appointments. In addition there is the possibility that some 2,000 former residents may return to complete their original assignments or establish themselves in other specialties. Thus with a normal civilian complement of 5,500 residents the approved hospitals may be called on to furnish a total of 12,000 or 13,000 residencies in the immediate postwar period.

Can this demand be met?

Under normal conditions the 660 civilian hospitals approved for residency training supply facilities for approximately 5,500 resident physicians. In the present survey 545 hospitals report 8,028 residencies.

It is apparent from these figures that many institutions have almost doubled their educational capacity for postwar training. If this degree of expansion is maintained, it should be possible to develop the required twelve or thirteen thousand residencies in the approved hospitals, especially if the potentialities of the internship hospitals are also taken into consideration.

The distribution of residencies in the present survey is given in table 1.

BASIC MEDICAL SCIENCES

There is evidence in the reports of the medical schools that careful attention is being given to the problem of supplying basic medical science instruction in relation to clinical specialties during the postwar period. Up to the present time 37 schools have indicated that facilities will be available for continued training in the preclinical fields. Twelve hospitals reported affiliations with medical schools to provide supplementary instruction in basic sciences, while 24 others indicated that courses of this type would be developed in their own departments of bacteriology and pathology. From the incomplete information now at hand it is apparent that 117 positions are available in anatomy, 124 in bacteriology, 135 in pathology, 96 in biochemistry and 123 in physiology.

POSTGRADUATE COURSES

Information received from 60 hospitals, 26 medical schools and the various state medical associations and departments of health indicates that 259 postgraduate courses have been organized which can accommodate a minimum of 4,522 physicians. The capacity is obviously much larger than the number indicated, however, for the size of the class was not specified in connection with 133 of the courses listed. The distribution of these educational opportunities is shown in table 2.

This study of postwar educational facilities will be continued so that at the close of the war the Council expects to have ready for distribution a printed list of all educational opportunities available to returning medical officers and especially planned for them. The achievement of this goal will depend in large measure on a continuation of the excellent cooperation of the hundreds of institutions which have been keeping the Council informed of their postwar plans.

ARMY

FLIGHT SURGEONS IN THE SOUTH PACIFIC

Flight surgeons who are to be assigned to various units of the 13th AAF assemblé at headquarters of the Air Force "somewhere in the South Pacific." They are, from left to right: First row: 1st Lieut. Daniel D. Dolce, Buffalo; 1st Lieut. Michael L. Gompertz, New York; Capt. Carl F. Wagner, Cincinnati; 1st Lieut. DeWitt C. Kissel, Pittsburgh; 1st Lieut. William C. Craig, Waynesboro, Pa. Second row: Capt. Law-

Flight surgeons in South Pacific

rence H. Siegel, Dallas, Texas; Capt. Alfred J. Krug, Maplewood, N. J.; Major Raymond H. Vunk, Charleston, S. C. (standing); Capt. Wilbur A. Smith, Philadelphia; 1st Lieut. Edward A. Backus, Milwaukee; 1st Lieut. John L. Meyers, Shillington, Pa. Third row: Capt. Bernard J. Goldman, Detroit; Capt. Bernard L. Kreilkamp, St. Cloud, Minn.; 1st Lieut. Charles E. Cook, North Manchester, Ind.; 1st Lieut. Allen P. Newman, Carleton, Mich.

AWARDED LEGION OF MERIT

The War Department announced on December 18 an award of the Legion of Merit to the following officers of the U. S. Army Medical Corps:

Lieut. Col. William R. Hallaran, formerly of Cleveland, for "exceptionally meritorious conduct in the performance of outstanding services in New Guinea. From Dec. 20, 1942 to Jan. 21, 1943 as surgeon of an advanced base Lieutenant Colonel Hallaran successfully maintained the health of the command by his tireless supervision of malaria control activities and by his

development of field sanitation technics, effectively adapted to the special difficulties encountered by troops operating in the jungle. As commanding officer of a portable hospital from Dec. 20, 1942 to May 11, 1943, under primitive conditions, he operated the hospital and rendered superior service in the treatment of tropical disease cases and numerous serious battle casualties. His exemplary devotion to the improvement of the health and living conditions of the troops raised the morale and personal efficiency of officers and men alike. Lieutenant Colonel Hallaran made a vital contribution to the development of this advanced base." Dr. Hallaran graduated from Western Reserve University School of Medicine, Cleveland, and entered the service Jan. 10, 1942.

Lieut. Col. Alva E. Miller, formerly of St. Louis, was awarded the Legion of Merit for "exceptionally meritorious conduct in the performance of outstanding services in New Guinea from Jan. 21, 1943 to Aug. 12, 1943. As surgeon of an advanced base, Lieutenant Colonel Miller was charged with organizing hospitalization, evacuation, tropical disease control and sanitation. With limited personnel and under adverse conditions of weather and terrain, he progressively lowered the sick rate of the troops, planned the hospitalization in connection with expansion of the base and personally explored the rough terrain for suitable sites. At all times he gave unstintingly of his time and maintained high professional standards. On many occasions of enemy air attack Lieutenant Colonel Miller, often working between bombing runs, personally directed the removal of casualties and gave emergency treatments. His services were an important contribution to the logistic support of the successful combat operations on the north coast of New Guinea." Dr. Miller graduated from Washington University School of Medicine, St. Louis, in 1934. He has been a regular army officer since 1939.

Major (then Captain) George S. Maxfield, formerly of Waco, Texas, was awarded the Legion of Merit for "Exceptionally meritorious conduct in the performance of outstanding service as Chief of x-ray service at Amchitka during the period of Jan. 22, 1943 to Aug. 25, 1943. Under most trying conditions of weather, lack of facilities and little assistance, he rendered excellent services from his department day and night during the initial phase of the landing. In addition to his own duties he volunteered his services and took personal charge of the erection of several buildings of the station hospital. Captain Maxfield set a high example to all men he worked with and through his leadership, energy and high devotion to duty contributed greatly to the development of the medical facilities at his station." Dr. Maxfield graduated from Baylor University College of Medicine, Dallas, Texas, in 1940 and entered the service July 1, 1941.

Major (then Captain) Maurice M. Steinberg, formerly of Omaha, was awarded the Legion of Merit for "Exceptionally meritorious conduct in the performance of outstanding services

in New Guinea from Sept. 2, 1942 to June 9, 1943. Major Steinberg volunteered for service in New Guinea at a time when the security of the island was seriously threatened. Assigned as chief of the Hospitalization and Evacuation Section, Office of the Surgeon, United States Advanced Base, he organized quickly and effectively the facilities for the hospitalization and staging of large numbers of sick and wounded. During the Papuan campaign he regulated the heavy traffic of patients with remarkable precision and speed. Major Steinberg also was largely responsible for the preparation of statistical material on the basis of which many problems of the Medical Department in New Guinea were solved. His technical proficiency, his energy and his executive talent were largely responsible for dealing successfully with a most difficult situation." Dr. Steinberg graduated from Creighton University School of Medicine, Omaha, in 1935 and entered the service Jan. 25, 1941.

THREE ARMY NURSES TO RETIRE

Lieut. Col. Elsie Neff, after serving thirty-three years in the Army Nurse Corps, will retire on March 31, 1944. A graduate of Princeton Sanatorium, Princeton, Ind., she has served in the capacity of chief nurse in widely scattered areas of the United States, saw duty in the Philippines both before and after World War I, and was stationed in Hawaii from 1926 to 1930. Colonel Neff is now principal chief nurse of Fitzsimons General Hospital, Denver, where she has been serving since 1938.

1st Lieut. Christina C. MacLauchlan will retire on Jan. 31, 1944 after twenty-six years in the Army Nurse Corps. Born in Canada, she received her nursing training at the Blackstone Hospital, Pawtucket, R. I., where she graduated in 1916 and became a citizen of the United States in 1920. Joining the Army Nurse Corps in 1918, she served eleven months with Base Hospital No. 60 at Bazoilles-sur-Meuse in France. She served in the Philippine Department from 1927 to 1929 and in the Hawaiian Islands from 1937 to 1939. At the present time she is stationed at Walter Reed General Hospital, Washington, D. C., where she was promoted to the grade of first lieutenant in February 1943.

1st Lieut. Clara W. Woodruff, who has served twenty-five and a half years in the Army Nurse Corps, will retire on Feb. 29, 1944. Graduating from Sayre, Pennsylvania's Peoples' Cooperative Hospital in 1913, she specialized as a laboratory technician, in which branch she has served throughout her career in the army. She joined the Army Nurse Corps in 1918 and served with Base Hospital No. 77 in Beaune, France, for seven months, for which she received the Victoria Medal. Her only other period of overseas service was in the Philippines from 1921 to 1923. She has served in large army general hospitals in the states from coast to coast and was promoted to the grade of chief nurse in 1942. Lieutenant Woodruff is stationed at the Letterman General Hospital, San Francisco.

MAJOR ANTHONY D. D'ALFONSO AWARDED AIR MEDAL

The War Department announced on December 15 the award of an air medal to Major Anthony D. D'Alfonso of the U. S. Army Medical Corps, formerly of Philadelphia, for "Meritorious achievement while participating in aerial missions over the Solomon Islands as a flight surgeon from December 1942 to May 1943. Major D'Alfonso took part in strike and search missions over Munda, Kahili and Rekato Bay areas, acquiring a total of one hundred and fifteen hours in combat operational flights. His vigorous prosecution of his duties as surgeon and his arduous efforts to gain a better understanding of the various combat factors enabled him to cope most intelligently with ailments from combat flying. Major D'Alfonso's sound judgment and devotion to duty contributed immeasurably to the physical well-being of combat crews and elicited the confidence and admiration of his subordinates and superiors. His voluntary actions displayed a fine example of the highest soldierly qualities and are in keeping with the traditions of the United States military service." Dr. D'Alfonso graduated from Hahnemann Medical College and Hospital of Philadelphia in 1939 and entered the service Nov. 8, 1940.

THE WILLIAM BEAUMONT GENERAL HOSPITAL

The William Beaumont General Hospital is one of the six named army general hospitals which were in operation prior to the present war. The hospital was opened on July 1, 1921 and is situated ½ mile north of the limits of the city of El Paso. In 1942, however, a number of new wards and detachment barracks were built, a large additional mess hall was added and a new administration building was completed and occupied late in 1941. The hospital buildings are of hollow tile and stucco. The wards are all of the two story type, connected by covered ramps. The capacity of the hospital at present is 1,750. The professional work done at the hospital is of a general nature, although special emphasis is placed on plastic surgery.

The hospital was named for William Beaumont, the U. S. army surgeon who in 1822 made the first notable contribution to our knowledge of the action of the gastric secretions, which he was enabled to study through a wound of the stomach which failed to heal.

Col. George M. Edwards has been in command of the hospital since May 12, 1937. Other medical officers on the staff are as follows:

ADMINISTRATION

Lieut. Col. Joe H. Sanderlin, executive officer.
Capt. Raymond L. Pendleton, registrar.
Capt. Thomas W. Torgerson, receiving and disposition officer.

SURGICAL SERVICE

Lieut. Col. Granville S. Delamere, chief.
Lieut. Col. John G. Manning, chief, orthopedic section.
Major William A. Bishop, Jr., assistant chief.
Capt. William C. Basom, ward officer.
1st Lieut. Richard C. Stauffer, ward officer.
Major Henry I. Berman, chief, genitourinary section.
1st Lieut. Robert O. Beadles, assistant chief.
Capt. William Dreyfuss, ward officer.
Major William H. Frackelton, chief general and plastic surgery section.
Major Lewis L. Hall, chief, obstetric and women's surgery section.
Capt. Charles Fields, ward officer.
Major Travis M. Martin, assistant chief, surgical service; chief, surgical section.
Harry A. Jakeman, ward officer, general surgery.
Major Oscar W. Thoeny, chief, eye, ear, nose and throat section.
Capt. George A. Filmer, ophthalmologist.
1st Lieut. David Bennett, ward officer.
Capt. Arthur P. Martini, chief, physical medicine and fever therapy section.
Capt. Jacobus D. McCulley, chief, operating room and anesthesia section.
1st Lieut. Dexter R. Branch, assistant chief.

MEDICAL SERVICE

Lieut. Col. George P. Denny, chief.
Lieut. Col. Lee Palmer, assistant chief.
Lieut. Col. George T. McMahon, chief, neuropsychiatric section.
Otto L. Bendheim, ward officer.
Major Joseph Bank, chief, general medicine section.
Capt. Louis J. Cheskin, ward officer.
Capt. John M. Gibbons, ward officer.
1st Lieut. Wayne P. Beardsley, ward officer.
Major Harry D. Clark, chief, pulmonary section; internal medicine.
Major Lester C. Feener, chief, cardiovascular section.
Hugh S. Espey, assistant chief.

LABORATORY SERVICE

Col. Albert G. Kinberger, chief.
Major Lester S. King, assistant.
Major William Reiner-Deutsch, San. Corps, assistant.
Capt. LaMonte A. Tucker, San. Corps, assistant.

DENTAL SERVICE

Major Crawford A. McMurray, D. C., chief.
Capt. Charles J. Bleke, D. C., assistant.
Capt. Raymond M. Davis, D. C., assistant.
Capt. Theodore G. Hollingsworth, D. C., assistant.
Capt. Milton L. Moore, D. C., assistant.
Capt. George H. Spicer, D. C., assistant.
Capt. Joseph E. Spiezo, D. C., assistant.
Capt. Kenneth W. Thomas, D. C., assistant.

X-RAY SERVICE

Major John H. Gilmore, chief.
Capt. Thomas K. Mahan, assistant chief.
1st Lieut. Harry I. Berland, assistant.

OUTPATIENT SERVICE

Lieut. Col. Wray R. Gardner, chief.
Major Maxwell Berman, assistant.
Capt. Clarence Bantin, assistant.

UNDERGROUND HOSPITAL AT CAMP JOSEPH T. ROBINSON

Underground hospitals are being built in some of our camps today so that the soldier, both medical and from other branches, will know exactly what to expect as a casualty overseas or as a medical attendant. Such a hospital, consisting of three wards, has been built at Camp Joseph T. Robinson, Arkansas. This underground hospital (the 55th General Hospital), is a training project and is practically bomb proof. It has been dug and carved from the earth and sandstone of the military terrain. The interior is finished with solid board floors, ceilings and side walls covered with insulation, and electricity and plumbing which is available in the field behind the lines of battle. Each of the three wards, connected by underground passages, is approximately 7 to 9 feet high, by 30 feet long and 15 feet wide. Three tunnels connect the passageways with the outside. Three feet of dirt rock protect the roofs of the wards. The hospital is completely equipped with x-ray equipment, blood plasma banks and the latest resuscitation elements. The hospital has its own electric generator in one of the passageways and running water in each room. Ventilators reaching to the upper ground have been constructed to serve also as emergency exits, and with the use of a "short litter," a metal frame which fits around the back of the patient, casualties can be hoisted to the open air. Lieut. Col. Charles C. Gill is in command at the Camp Joseph T. Robinson Hospital.

LIEUT. CHARLES C. SMITH AWARDED SILVER STAR

Lieut. Charles C. Smith, formerly of Charleston, S. C., has been awarded the Silver Star for gallantry in action. The citation accompanying the award read as follows: "On the 10th of July 1943 the ship on which First Lieutenant Smith was a passenger was bombed and strafed by German planes as it prepared to beach near Licata, Sicily. One halftrack was set afire and Lieutenant Smith directed and personally assisted the fire-fighting crew. He spent the remainder of the day inside the ship caring for the wounded, completely disregarding further bombing and strafing attacks. His calm, courage, absorption

to duty in the face of danger, and above all his coolness under fire, was an inspiration to all army and navy personnel on board and helped immeasurably in the sustaining of a high morale during a difficult operation." Dr. Smith graduated from the Medical College of the State of South Carolina, Charleston, in 1941. He entered the service July 8, 1941 and is now serving with the armored field artillery unit of the Fifth Army in Italy.

PRISONERS OF WAR

Word has recently been received by the wife of Lieut. Orville L. Barks, formerly of Sanford, Fla., that he is a prisoner of war at Oflag 64, Germany, having been captured in Tunisia in February. Dr. Barks graduated from Washington University School of Medicine, St. Louis, in 1938 and entered the service in August 1940.

Information has recently been received that the following medical corps officers are being held prisoners of war in Concentration Camp P. G. 21 in Italy:

Capt. Francis Gallo, formerly of Winsted, Conn., who graduated from Jefferson Medical College of Philadelphia in 1934 and entered the service in April 1941.

Capt. Wilbur E. McKee, formerly of Columbus, Ohio, who graduated from Ohio State University College of Medicine in 1930 and entered the service in May 1941.

Capt. Henry J. Wynsen, formerly of Youngstown, Ohio, who graduated from Loyola University School of Medicine, Chicago, in 1941 and entered the service in September 1941.

Capt. Thomas E. Corcoran, formerly of Rock Rapids, Iowa, who graduated from the State University of Iowa College of Medicine, Iowa City, in 1938 and entered the service in February 1941.

FLIGHT SURGEONS' ASSISTANTS

A class of one hundred flight surgeons' assistants completed the course in aviation medicine at the School of Aviation Medicine, Randolph Field, Texas, November 27. Brig. Gen. Eugen G. Reinartz, U. S. Army, is commandant of the school.

NAVY

MOBILE LABORATORY TO TEST NUTRI- TIVE VALUE OF NAVY MEN'S DIETS

A new mobile unit has been created by the Naval Medical Research Institute, Bethesda, Md., in order to obtain detailed information on field nutrition practices. It is designed to determine accurately the nutritive values of foods used in navy menus as they are served. The mobile nutrition unit consists of a small truck which has been converted to afford facilities for collection and preservation of food samples from mess halls. It is equipped with a quick freezing unit to preserve certain food samples which will be transported to the Naval Medical Research Institute for analysis. Equipment is also provided for the determination of vitamin C content. The first field studies were conducted at Quantico, Va., under the direction of Lieut. Comdr. Clive M. McCay of the Naval Medical Research Institute, who in civilian life is professor of nutrition at Cornell University and lives in Ithaca, N. Y.

CAPT. LOUIS H. RODDIS RECEIVES WELLCOME AWARD

Capt. Louis H. Roddis (MC), U. S. Navy, has received the Sir Henry Wellcome award of 1943 of the Association of Military Surgeons of the United States. Thirteen manuscripts were submitted in competition. Dr. Roddis was the fourth successive naval officer to win this award. He graduated from the University of Minnesota Medical School, Minneapolis, in 1913. He is at present on duty at the Naval Training Station, Newport, R. I. The second award was given to Lieut. Comdr. Samuel G. Berkow (MC), U.S.N.R., Naval Hospital, Norfolk,

Va., who received a life membership in the association. Honorable mention for third place was awarded to Lieut. Col. Roswell K. Brown, M. C., A. U. S., stationed at Stanford University, Calif., and to Capt. Irving M. Artel, 230th Station Hospital, Camp Van Dorn, Mississippi.

WORK OF NAVY MEDICAL CORPS PERSONNEL ON TARAWA

With the aid of three navy medical corpsmen, Lieut. Herman R. Brukart, formerly of Menominee, Mich., is reported to have treated more than 100 men in a "pill box" hospital, with only four casualties, during the first thirty-six hours after marines struck the Japanese Gilbert Islands' bastion. The little pill box hospital was situated directly on the front lines the first two days of the brief but bitter Tarawa fighting. But despite the fact that constant Japanese machine gun bullets thudded in the little doorway, the naval crew refused to relax its efforts to save Leatherneck lives. Many of the marines with slight wounds remained around the pill box for hours helping carry the more seriously wounded in to the doctors.

NAVY PERSONALS

Capt. Joel J. White, Nashville, who served fourteen months in the South Pacific as medical officer in command of Base Hospital No. 3, will assume the duties as medical officer of the Norfolk Navy Yard, replacing Capt. James F. Hooker, who has been detached and assigned to foreign duty. Dr. White, who has been in the United States Navy for twenty-six years, started a branch hospital at Guadalcanal and spent August, September and October 1942 on Guadalcanal. He has received

the Presidential Unit Citation for his task force in the South Pacific with a star indicating engagements, the Victory Medal, the South Pacific Campaign Ribbon with star and the Haitian Legion of Merit and Honor Medal. Dr. White graduated from Vanderbilt University School of Medicine, Nashville, in 1916 and was commissioned a junior grade lieutenant in the United States Navy in 1917.

Comdr. Gordon Bennett Tayloe, formerly of Aulander, N. C., recently left the United States to become head of a hospital unit somewhere in foreign territory. Dr. Tayloe graduated from the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, in 1927 and on completion of his internship was commissioned in the Navy

Medical Corps. Since that time he has seen service at sea and in hospitals in port cities of Washington, Portsmouth, Long Beach, Brooklyn, Philadelphia and Guam. He escaped from Guam just in time to avoid capture by the Japanese as they closed in on the islands of the Pacific. Since that time he has received special training at the Mayo Clinic and served as head of a naval hospital in Philadelphia before going overseas.

Dr. Joseph H. Barach, medical director of the Falk Clinic at the University of Pittsburgh School of Medicine, was guest speaker at the meeting of the Staff of the United States Naval Hospital at Quantico, Va., November 29. The subject of his address was "Etiologic Factors in the Transition from Mild to Severe or Fatal Diseases."

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their Procurement and Assignment Service quotas for the early months of 1944:

(Continuation of list in THE JOURNAL, December 25, p. 1124)

CONNECTICUT

Undercliff, Meriden State Tuberculosis Sanatorium, Meriden. Capacity, 308; admissions, 392. Dr. Cole B. Gibson, Medical Director (resident—tuberculosis).

MINNESOTA

Swedish Hospital, Minneapolis. Capacity, 362; admissions, 10,037. Mr. R. K. Swanson, Superintendent (1 intern).
Bethesda Hospital, St. Paul. Capacity, 200; admissions, 6,369. Rev. L. B. Benson, Superintendent (3 interns).
St. Joseph's Hospital, St. Paul. Capacity, 282; admissions, 9,259. Sister St. Ignatius, R.N., Superintendent (1 intern).

OHIO

Deaconess Hospital, Cincinnati. Capacity, 200; admissions, 5,200. Mr. William F. Frersing, Superintendent (2 interns).
Massillon State Hospital, Massillon. Capacity, 3,420; admissions, 763. Dr. Arthur G. Hyde, Medical Superintendent (assistant resident—psychiatry).
Lucas County General Hospital, Toledo. Capacity, 325; admissions, 3,215. Mr. Robert R. Stewart, Acting Superintendent (2 interns).

PENNSYLVANIA

Mercy Hospital, Pittsburgh. Capacity, 680; admissions, 14,128. Sister Anna Marie, R.N., Superintendent (2 residents).
Mercy Hospital, Wilkes-Barre. Capacity, 220; admissions, 4,586. Sister Mary Avellino, R.N., Superintendent (4 interns).

VIRGINIA

Retreat for the Sick, Richmond. Capacity, 120; admissions, 3,913. Miss Alice T. Collins, R.N., Superintendent (3 residents).

WEST VIRGINIA

Chesapeake and Ohio Hospital, Huntington. Capacity, 185; admissions, 2,900. Miss Eleanor D. Koch, R.N., Superintendent (resident—medicine).

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

Among the subjects scheduled for early presentation under the auspices of the Wartime Graduate Medical Meetings are the following at Indiantown Gap, Pa.: Dermatology, Dr. J. V. Klauder and Lieut. Comdr. H. E. Twining, January 6; Chest Surgery, Dr. J. S. Rodman, January 13; Dysenteries, Dr. H. L. Bockus, January 20; Malaria, Dr. W. Savitz and Comdr. G. W. Smith, January 27.

At Fort Monmouth, N. J.: Gastrointestinal Hemorrhages, Lieut. Comdr. J. T. Eads and Capt. S. B. Lapin, January 5; Dysenteries, H. L. Bockus and Capt. S. B. Lapin, January 12; Psychosomatic Medicine, Dr. B. P. Weiss and Major H. Swire, January 19 and 26.

At the Naval Hospital, Philadelphia: Laboratory Medicine, Dr. J. Eiman and Lieut. Comdr. H. M. Dixon, January 7; Peripheral Vascular Disease, Dr. M. Naide and Lieut. Comdr. G. C. Griffith, January 21.

At Camp Lee, Va.: Psychoneurosis, Maladjustment, Neuro-psychiatry, Dr. O. B. Darden, January 7; Dysenteries, Dr. J. A. Scherer, January 14; Newer Drugs and Their Uses in Practice, Dr. H. B. Haag, January 21; Diagnosis and Treatment of Contagious Diseases, Dr. H. Walker, January 21.

At the U. S. Naval Hospital and the U. S. Naval Academy Dispensary, Annapolis, Md.: Psychoneurosis Among the Armed Forces, Dr. R. H. Guthrie, January 21; Rickettsia, Diagnosis, Treatment and Prevention, Dr. R. E. Dyer, February 18.

ARMY GENERAL PRAISES NAVY DOCTOR

Lieut. Comdr. Henry F. Strongin, formerly of New York City and now stationed at Great Lakes (Ill.), was highly praised by Major Gen. Albert W. Kenner in a personal letter which read as follows: "It was my intention to bring to the attention of the Naval Task Force surgeon the efficient manner in which you administered to our men during the trip across and the

assault phase of our landing at Fedala. You were extremely cooperative with the Army medical personnel and I have no hesitance in stating that because of your efforts our men were in excellent physical condition when they engaged the enemy. Because of the exigencies of combat and the fact that the fleet sailed before I had anticipated, I failed to express my appreciation formally, through official channels." Dr. Strongin graduated from George Washington University School of Medicine, Washington, in 1921 and entered the service on Jan. 22, 1942.

PUBLIC HEALTH UNDER HITLER

DNB of October 6 states that, in order to insure the efficient employment for the members of the medical professions, all doctors, dental surgeons, dispensing chemists, midwives, dentists and dental mechanics admitted to practice who have to leave their place of work or residence because of a terror raid must report without delay to the competent professional organization in accordance with instructions issued by the reich health leader, Dr. Conti, or by their professional organization. It is in the interest of these professionals themselves that they report, since they might otherwise suffer losses.

The October 8 issue of *Le Petit Journal* quotes *Le Petit Dauphinois*: "At least 70 to 80 per cent of children show symptoms of rickets, chiefly due to the inadequate supply of milk. The deficiency of antirickets vitamins could be remedied through ray activated milk costing only a few centimes more per liter, which is not expensive when it is a matter of saving many generations. Unfortunately, a decree of Dec. 22, 1936, promulgated at the Medical Academy's request, practically prohibits a large scale use of ray activated milk. Under this decree, chemists alone may sell such milk, and naturally at prohibitive prices. The government should at once repeal the decree, which is now less justified than ever."

ORGANIZATION SECTION

OFFICIAL NOTES

THE 1944 CHICAGO SESSION

Section Representatives to the Scientific Exhibit

Following is a list of representatives to the Scientific Exhibit from each section of the Scientific Assembly:

- Practice of Medicine—Dr. Thomas C. Garrett, 3803 Oak Road, Germantown, Philadelphia.
- Surgery, General and Abdominal—Col. Grover C. Penberthy, Headquarters Seventh Service Command, Omaha.
- Obstetrics and Gynecology—Dr. Fred H. Falls, University of Illinois College of Medicine, 1853 West Polk Street, Chicago 12.
- Ophthalmology—Dr. Georgiana D. Theobald, 120 Medical Arts Building, Oak Park, Ill., chairman, Section Committee on Scientific Exhibit; Dr. A. B. Reese, New York; Dr. Derrick Vail, Cincinnati.
- Laryngology, Otology and Rhinology—Dr. Paul H. Holinger, 700 North Michigan Avenue, Chicago.
- Pediatrics—Dr. Sterling H. Ashmun, 117 South Main Street, Dayton, Ohio.
- Experimental Medicine and Therapeutics—Dr. Robert W. Wilkins, Evans Memorial Hospital, 65 East Newton Street, Boston.
- Pathology and Physiology—Dr. F. W. Konzelmann, Temple University Hospital, Philadelphia.
- Nervous and Mental Diseases—Dr. F. P. Moersch, Mayo Clinic, Rochester, Minn.
- Dermatology and Syphilology—Dr. Hamilton Montgomery, 102 Second Avenue S.W., Rochester, Minn.
- Preventive and Industrial Medicine and Public Health—Dr. Paul A. Davis, 1436 Delia Avenue, Akron, Ohio.
- Urology—Dr. John H. Morrissey, 40 East Sixty-First Street, New York.
- Orthopedic Surgery—Dr. Fremont A. Chandler, 6 North Michigan Avenue, Chicago.
- Gastro-Enterology and Proctology—Dr. Grant H. Laing, 104 South Michigan Avenue, Chicago.
- Radiology—Dr. S. W. Donaldson, 326 North Ingalls Street, Ann Arbor, Mich.
- Anesthesiology—Dr. E. A. Rovenstine, 477 First Avenue, New York.

Applications for space in the Scientific Exhibit close on February 10. Blanks may be obtained from the section representatives or from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago 10.

THE FARM FOUNDATION

The Farm Foundation was created in 1933 by a group of men who deeply desired a better life for the rural people of this nation. The founders included Alexander Legge and Frank O. Lowden. When he died, Alexander Legge left one half of his estate to the Farm Foundation. It is administered by a board of trustees which includes representatives of government, farmers, manufacturers, merchants, transportation and the universities. The director is Henry C. Taylor.

In its report covering the first ten years appears the following statement regarding medical care and the health of rural people:

In 1938 the Farm Foundation reviewed the work of medical care and health for rural people that was being carried on at various places in the United States and concluded that there was real need for an educational program to stimulate rural people to understand and solve for themselves the problems peculiar to each area.

The director of the Farm Foundation visited Nebraska and learned from rural women at a meeting in Lincoln that they would like help in developing a program of better medical care for their state.

"DOCTORS AT WAR" OPENS JANUARY 8

Doctors at War, the ninth series of dramatized network broadcasts by the American Medical Association and the National Broadcasting Company, opens January 8 and will run for approximately twenty-six weeks.

The series will continue to interpret the role of the doctor at war in a broad sense. Not only the doctor in uniform with the fighting forces, but the doctor on the home front, in industry and in public health service will be included. "All doctors are doctors at war wherever they may serve" will be the underlying theme of the program.

The program scripts will again be written by the veteran ace of medical script writers Mr. William J. Murphy, who has written for the American Medical Association all but two series and a portion of a third of previous dramatized broadcasts. The NBC orchestra will be conducted by Joseph Gallichio, well known to radio listeners. Production will be by Martin Wagner, who directed the second series of Doctors at War, predecessor program of Doctors at War. Distinguished doctors from the armed forces, from public health agencies and from civilian life will appear as summarizers on many of the programs; narrator will be Dr. W. W. Bauer.

The first four programs, with dates, titles and speakers, are as follows:

- January 8. "Wings for the Wounded." Speaker, Major Gen. Norman T. Kirk, M. C., Surgeon General, United States Army.
- January 15. "Abandon Ship." Speaker, Rear Admiral Ross T. McIntire (MC), chief, Bureau of Medicine and Surgery, United States Navy.
- January 22. "Honorable Discharge." Speaker to be announced.
- January 29. "Dangerous Hours." Speaker, Dr. Thomas Parran Jr., Surgeon General, United States Public Health Service.

Subsequent program announcements will appear in THE JOURNAL weekly and in HYGEIA monthly.

SOUTHWESTERN MEDICAL SCHOOL ON APPROVED LIST

The Council on Medical Education and Hospitals of the American Medical Association has voted to include the Medical School of the Southwestern Medical Foundation at Dallas, Texas, in its list of approved medical schools.

The Farm Foundation then secured the cooperation of the University of Nebraska. The university, with financial aid furnished by the foundation, undertook the project on medical care and health of rural people. The work was started in July 1939 under the auspices of the Extension Service in Agriculture and Home Economics of the University of Nebraska. Miss Elin L. Anderson, recommended by the Farm Foundation, was put in charge.

Work on the Nebraska project was started in Dawson County. The method of approach was educational. The objective was to get farm people and their doctors to confer together on the best method of securing a more adequate health and medical program. As a result of these conferences, the rural people of Dawson County became interested in developing prepayment plans for medical care as a means of providing for themselves preventive as well as curative medical services. At Farnam in one corner of the county a medical cooperative was formed in which families pay \$36 a year for general medical, surgical and hospital care. When developments of the same character in other parts of the county were blocked by some of the leaders of the county medical society, the rural people expressed the need for stronger support from their college of agriculture and the state medical society.

In the second year the educational program was extended to the entire state of Nebraska. A circular "Do We Want Health?" prepared by Miss Anderson was studied in the 1,700 home demonstration clubs in the state.

This study stimulated such interest that many round table conferences on medical care were held throughout the state. Action programs along various community health lines developed in a number of counties, but little progress was made in solving the economic problems of medical care.

The turning point in the study was reached in August 1941, when, following a state round table conference, a State Health Planning Committee was set up, composed of official representatives of the medical and dental professions, the university and certain rural organizations. This state committee gave first attention to aiding the people in sparsely settled areas in providing for themselves more adequate health services. By June 1942 the local people of Thomas County had set up a cooperative health association. For \$30 a year families receive the services of a well qualified physician and a public health nurse who make regular weekly visits to the five small communities. They cover an area of 1,000 square miles, rendering medical care and conducting programs of disease prevention and health education. This project has attracted wide attention through articles describing it in the January 1943 issues of the *Country Gentleman* and the *Farm Journal and Farmer's Wife*.

Members of the Nebraska state committee have assisted also in setting up a medical project sponsored by the United States Department of Agriculture. In Hamilton County, Neb., all farm families may pool 6 per cent of their net cash income with a maximum per family of \$57 for general medical, surgical and hospital care, some dental services and drugs. This project has been under way since August 1942.

The State Health Planning Committee has also given attention to enabling legislation for local public health departments. Some members of the committee were responsible for preparing the bill, planning hearings before the legislature's public health committee and preparing educational bulletins and fliers describing the need for this legislation.

Meanwhile the Nebraska Extension Service in Agriculture and Home Economics continues with a broad educational program on the medical care and health of rural people. A circular "Health on the Home Front," prepared by Miss Anderson for study by all the home demonstration clubs, has been a timely guide for wartime community health programs.

Interest in this project has spread far beyond Nebraska. Miss Anderson has been asked to serve on the Great Plains Regional Committee on Health and has already begun basic planning for this whole area. Ohio has set up a state health planning committee which has had Miss Anderson's services on three different occasions to help them think through the approach to their problem and plan the first steps in an educational and action program. Iowa and other states have made similar requests for help.

War has accentuated the problems of rural medical care so that everywhere there is a growing concern with basic planning during the war for more adequate postwar rural health programs.

The Farm Foundation believes that there are many different ways in which more adequate medical care can be acquired by rural people. Because the Farm Foundation believes that permanent improvement results from local initiative and will rather than from something superimposed from the outside, it does not urge the adoption of any specific plan or program. It holds that its function is to stimulate local interest in studying local needs and to help in the investigation of ways and means suited to the given community. It confines its efforts strictly to educational methods.

The bibliography follows:

- Anderson, Elin L.: *Do We Want Health?* University of Nebraska College of Agriculture and U. S. Department of Agriculture Cooperating, Extension Circular 1021. Lincoln, Neb., September 1940; 32 pages.
- Health on the Home Front, University of Nebraska College of Agriculture and U. S. Department of Agriculture cooperating, Extension Circular 1923. Lincoln, Neb., 1942; 14 pages.
- "Family Health Plan," q. v., was prepared to supplement this circular.
- Family Health Plan, University of Nebraska College of Agriculture and U. S. Department of Agriculture cooperating, Supplement 26. Lincoln, Neb., 1942; 8 pages.
- Prepared to supplement "Health on the Home Front," q. v. Extension Circular 1023.
- Mobilizing Home Forces for a Health Campaign, University of Nebraska College of Agriculture and U. S. Department of Agriculture cooperating, Extension Circular 5-92. Lincoln, Neb., August 1942; 8 pages; mimeographed.

- Nebraska's Extension Service on the Health Front, *J. Home Econom.* 35: 137-141 (March) 1943.
- Streeter, Carroll P.: Sand Hills Medicine, *Farm J. and Farmer's Wife* 67: 38-39 (Jan.) 1943.
- Mullen, Eileen: No Doctor Shortage Here: Enterprising ranchers in the Sand Hills of Nebraska have found the way to get and keep a doctor and a nurse in their thinly populated country. *Country Gentleman* 113: 16, 68 (Jan.) 1943.

NEW ADVISORY MEMBERS FOR CHILDREN'S BUREAU

The United States Children's Bureau announces the appointment of the following new members of the Children's Bureau Advisory Committee on Maternal and Child Health Services. These members were appointed in response to the resolution adopted by the Advisory Committee on Oct. 21, 1943, requesting that the committee be enlarged by the appointment of at least five physicians actively engaged in the private practice of medicine:

- Dr. Sterling H. Ashmun, Dayton, Ohio.
Dr. Harvey F. Garrison, Jackson, Miss.
Dr. Eleanor Harvey, Newport News, Va.
Dr. John Preston, Tryon, N. C.
Dr. S. A. Thompson, Camden, Ark.
Dr. George D. Cannon, New York.

In addition, the following members of the Children's Bureau Commission on Children In Wartime have been appointed ex officio on the Advisory Committee on Maternal and Child Health Services:

- Dr. Frederick H. Allen, Philadelphia.
Dr. Leona Baumgarten, New York.
Dr. Reginald M. Atwater, New York.
Dr. Franklin P. Gengenbach, Denver.
Dr. Joseph S. Wall, Washington, D. C.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—H. R. 149 has been reported to the Senate, a bill to fix a reasonable definition and standard of identity of certain dry milk solids. H. R. 3687 has been reported to the Senate with amendments, a bill to provide revenue. As reported by the Senate, the bill retains the provision under which many associations now exempt from federal income taxes under section 101 of the Internal Revenue Code will be required to file annually informational returns with the Commissioner of Internal Revenue. Associations exempted under section 101(6) and section 101(7), other than certain educational and charitable organizations, will be obligated to file such returns. The bill does not contemplate that the income of such exempt organizations will at this time be subjected to tax. The Senate Committee on Education and

Labor has been conducting hearings on S. 1509, introduced by Senator Thomas, Utah, a bill to provide for the education and training of members of the armed forces and the merchant marine after their discharge or conclusion of service.

Bills Introduced.—H. R. 3846, introduced by Representative Barden, North Carolina, and H. R. 3850, by Representative Outland, California, provide for education and training of members of the armed forces and merchant marine after separation from service. H. R. 3892, introduced by Representative Miller, Connecticut, provides that prior to trial of any member of the land forces before a general or special court martial or of any member of the naval forces before a general or summary court martial, he shall be given a psychiatric examination, under the direction of the court, to determine his mental condition and the existence of any mental disease or defect.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

District Meeting.—The Ninth Councilor District Medical Society was addressed in Harrison, December 8, by:

Dr. Ruth Ellis Lesh, Fayetteville, Torsion of Ovarian Cysts in Children.
Dr. Francis T. H'Doubler, Springfield, Mo., Perforated Peptic Ulcer.
Dr. Urban J. Busiek, Springfield, Immunization Procedure.
Dr. Walter S. Sewell, Springfield, Pyelitis.
Dr. William A. Fowler, Fayetteville, The Physiology and Mechanism of Labor.

The Ninth Councilor District is made up of Baxter, Boone, Carroll, Marion, Newton and Searcy counties.

CALIFORNIA

Course in Venereal Diseases.—The University of Southern California School of Medicine, cooperating with the Los Angeles Department of Health and the state department of public health, opened a course in the diagnosis and treatment of syphilis and gonorrhea, January 3, to continue through January 14. Qualified licensed physicians are eligible for the course, which is given with the approval of the U. S. Public Health Service and the Los Angeles County Medical Association.

COLORADO

Consultation Fees of Teachers Revert to Institutions.—The board of regents of the University of Colorado, Denver, on November 19 unanimously approved the employment of full time teachers in the departments of medicine, surgery, obstetrics and gynecology and pediatrics with the understanding that all fees, if any, received by these teachers for consultation work be turned into the university treasury, the teachers' salaries to be fixed to take into account the fact that these men are not entitled to such fees themselves. This action was taken after earlier consideration and agreement "that it is very detrimental to the future of the medical school for a full time man to be allowed to carry on the private practice of medicine and consultation for his own gain," a conclusion reached at a meeting of the public policy committee of the Colorado State Medical Society with representatives of the medical school and the university. The committee went on record (1) favoring the raising of salaries of all full time heads of departments and their associates in the school of medicine, the Colorado General Hospital and the Colorado Psychopathic Hospital, Denver, to an adequate figure and (2) allowing full time men the privilege of consultation when it is arranged for through the head of the department and requested by a duly licensed doctor of medicine, the fees for the consultation to be collected by the medical school and the two hospitals and turned in to their respective funds.

CONNECTICUT

Russell Chittenden Dies.—Russell Henry Chittenden, Sc.D., emeritus director of the Sheffield Scientific School at Yale University, New Haven, died at his home in New Haven, December 26. Dr. Chittenden, who in 1934 received the honorary M.D. degree from the Connecticut State Medical Society, was a pioneer in the field of nutrition and was credited with the discovery of protein in food. Dr. Chittenden was a senior in the scientific school at Yale in 1875 when he discovered the presence of glycocoll and glycogen in scallops, said to be the first time a free amino acid in living tissue had been isolated. Dr. Chittenden was the author of a number of books on his subject and in 1907 published "The Nutrition of Man," which became a standard work on nutrition. He received his Ph.B. at the Yale Scientific School in 1875, a Ph.D. in 1880 and later degrees from other universities. He was a member of the staff at the scientific school from 1875, serving as director from 1898 to 1922, when he retired. He had once served as a member of the referee board of consulting scientific experts to the secretary of agriculture and had, in addition to holding memberships in numerous scientific groups, served as president of the American Society of Naturalists, American Physiological Society and the American Society of Biological Chemists. He became an honorary fellow of the New York Academy of

Medicine in 1930. The honorary degree of doctor of medicine conferred by the Connecticut State Medical Society was the first time in one hundred and twenty-one years that the society had exercised this honor. The citation read:

This honor, now held by no living man, is about to be conferred upon you in recognition of your valuable contributions to our knowledge of the human body and because of the inspiration derived from your instruction by many who later achieved marked success in the practice of medicine.

ILLINOIS

Graduate Conference.—On December 16 the Illinois State Medical Society sponsored the Northern Illinois Post Graduate Conference at the Fort Armstrong Hotel, Rock Island. The speakers were Dr. Walter H. Nadler, Chicago, on "Nonsurgical Conditions of the Abdomen," Dr. G. Henry Mundt, Chicago, "Ear, Nose and Throat Conditions" and Dr. Lowell D. Snorf, Evanston, "The Discriminate Use of the Sulfonamides."

Chicago

Dental Society Award Goes to Dr. Luckhardt.—The Ohio State Dental Society at a meeting in Cleveland, November 8, presented its Callahan Memorial Award to Dr. Arno B. Luckhardt, professor of physiology, University of Chicago School of Medicine, for his contributions to humanity and the healing arts. The award is a gold medal.

The Fenger Lecture.—Dr. Howard T. Karsner, professor of pathology and director of the Institute of Pathology, Western Reserve University School of Medicine, Cleveland, will deliver the eighth Christian Fenger Lecture of the Institute of Medicine of Chicago and the Chicago Pathological Society at the Palmer House on February 14. Dr. Karsner's subject will be "Calcific Aortic Stenosis."

INDIANA

Appointments in Physical Therapy.—Drs. George J. Garceau and James S. Battersby, members of the staff of Indiana University Medical Center, Indianapolis, have been appointed medical supervisors of the physical and occupational therapy departments at the center. The directorship of the two departments was recently made vacant by appointment of Mrs. Winifred C. Kahmann as superintendent of the newly created occupational therapy unit in the reconditioning division in the surgeon general's office of the U. S. Army. Dr. Garceau, associate professor of orthopedic surgery in the school of medicine and chief orthopedic surgeon at the James Whitcomb Riley Hospital for Children, will have medical supervision of physical therapy and Dr. Battersby, resident surgeon at the center, will have medical supervision of the occupational therapy department.

KENTUCKY

New Health Center.—On October 5 the new quarters of the preventive section of the Louisville and Jefferson County Health Department were formally dedicated. The building cost \$113,369 and is located adjacent to the Louisville General Hospital. It will house the director of health, assistant directors in charge of communicable disease control, school health, home medical care and clinics, nursing bureau, maternal and child health bureau, health education and library, food and sanitation division, general preventive clinic and venereal disease control bureau. A feature of the new building includes a general library, consisting at the present of about 500 volumes in addition to bound periodicals and encyclopedias. Prior to the installation of the library the various divisions kept their own reference books.

LOUISIANA

Hull Award Goes to Senior Student.—Dr. Herbert Derman, a member of the senior class of the Louisiana State University School of Medicine, New Orleans, was presented with the Hull Award during the annual banquet of the Louisiana State University Society of Medical Sciences. Dr. Derman is also president of the society. The recipient for the award is selected by vote of members of the society on the basis of scholastic attainments and those qualities considered most desirable in the practice of medicine.

Dr. Schenken Gives Chaillé Oration.—Dr. John R. Schenken, professor of pathology and bacteriology, Louisiana State University School of Medicine, New Orleans, gave the annual Stanford E. Chaillé Memorial Oration December 16. The subject was "The Carcinogenic and Carcinostatic Effects of Estrogenic Substances: A Study of the Changes in the Mammary and Prostate Glands." The lecture is sponsored

by the Orleans Parish Medical Society to perpetuate the memory of Dr. Chaille. This is the first time that a member of the society has given the lecture, which was established in 1926.

Branch Meeting on Clinical Research.—The Southern sectional meeting of the American Federation for Clinical Research was held at Charity Hospital, New Orleans, December 3-4. Among the speakers were:

- Dr. John S. Harter, Jackson, Miss., The Prevention of Empyema Following Lobectomy for Bronchiectasis.
- Dr. Wallace Marshall, Mobile, Ala., Pathogenesis of Keloids with Clinical Applications in Medicine and Surgery.
- Drs. Byron E. Hall, Malcolm M. Hargraves and Charles H. Watkins, Rochester, Minn., Treatment of Polycythemia Vera with Radioactive Phosphorus.
- Dr. Joseph S. D'Antoni, New Orleans, Diodoquin Therapy in Amebiasis.
- Dr. William K. Purks, Vicksburg, Miss., Postural Hypotension.
- Dr. John C. Henthorne, Jackson, Fibrous Tumors of the Female Breast.
- Dr. John B. Johnson Jr., Washington, D. C., Physiologic and Clinical Effects of Acacia in the Treatment of Nephrotic Edema.

MASSACHUSETTS

Licenses Revoked.—The Massachusetts Board of Registration in Medicine on November 19 revoked the license to practice medicine of Dr. Aaron O. Bernstein, Athol, because of misconduct in the practice of his profession. The license of Dr. Manford R. Spalding was revoked October 6. Dr. Spalding had been found guilty of narcotic charges and sentenced to six months in the House of Correction in Salem.

The Dunham Lectures.—Dr. Frank Macfarlane Burnet, assistant director and head of the virus department, Walter and Eliza Hall Institute of Research in Pathology and Medicine, Royal Melbourne Hospital, Melbourne, Australia, spoke under the Edward K. Dunham Lectureship for the promotion of the medical sciences at Harvard Medical School, Boston, January 10, 12 and 14, on "Some Virus Diseases of Man—Evolutionary and Ecological Considerations." Individual titles will be "The Origins of Human Infectious Disease," "Herpes and Poliomyelitis" and "Influenza."

Obstetric Meeting.—The New England Obstetrical and Gynecological Society held its fifteenth annual meeting at the Harvard Club, Boston, December 8. The program consisted of clinics and pathologic conferences and included:

- Dr. Louis E. Phaneuf, Boston, Complete Tears of the Perineum and Rectovaginal Fistulae.
- Dr. Roy J. Heffernan, Brookline, Mass., The Use of the Sulfanilamide Gauze Pack in Obstetrics and Gynecology.
- Dr. Maurice O. Belson, Boston, The Diagnosis of Early Carcinoma of the Cervix.
- Dr. S. Charles Kasdon, Boston, The Rh Factor in Obstetrics and Gynecology.
- Dr. Philip B. Keitlen, Pittsburgh, X-Ray Pelvimetry on the Obstetrical Service of a General Hospital.
- Dr. Arthur T. Hertig, Boston, Spontaneous Abortion—Pathogenesis and Treatment.
- Dr. John Rock, Boston, The Incidence of Tuberculous Endometritis in Endometrial Biopsies for the Diagnosis of Infertility.
- Dr. Edwin F. Daily, Washington, D. C., Emergency Maternity and Infant Care Programs.

MICHIGAN

Changes in Health Officers.—Dr. John W. O'Neill, St. Charles, has been appointed health officer of district number 5, including Nawaygo, Lake and Oceana counties, succeeding Dr. Albert C. Edwards. Dr. O'Neill's headquarters will be in White Cloud.—Dr. Lars W. Switzer, Manistee, resigned as director of the Manistee-Benzie County health department December 1 to become associated with General Motors Corporation, Bay City.

Battle Creek Sanitarium Continues.—The Battle Creek Sanitarium, operating in a group of buildings on the west side of Washington Avenue, Battle Creek, will continue its activities, carrying out the wishes of its late director, Dr. John H. Kellogg. Late in 1942 the activities of the sanitarium were transferred to this group of buildings after the physical plant of the sanitarium had been converted into the Percy Jones General Hospital by the government. One building had been built for sanitarium purposes and had been used as an annex. Another building with a gymnasium, library rooms, assembly hall, administration offices and laboratories had been built and used by Battle Creek College, which suspended operation a number of years ago on account of financial difficulties. A third building gives the sanitarium accommodations of about 300 beds. Despite the fact that the main buildings had been transferred to military purposes, the activities of the sanitarium have been going on. The work of the sanitarium was not interrupted for even one day during the removal.

MISSISSIPPI

New Members of Board of Health.—Dr. Reuben B. Caldwell, Baldwyn, has been appointed a member of the state board of health to succeed Dr. James W. Lipscomb, Columbus, president of the board since 1932, and Dr. Paul G. Gamble, Greenville, will succeed Dr. Leonidas B. Austin, Rosedale, a member of the board for nineteen years.

MISSOURI

The Terry Lectures.—At a meeting of the St. Louis Medical Society December 21, lectures under the Robert J. Terry Lectureship were presented by Dr. Henry Pinkerton, St. Louis, on "Typhus Fever, Rocky Mountain Spotted Fever and Other Rickettsial Diseases" and Comdr. Alphonse McMahon and Lieut. Comdr. James M. Macnish (MC), U. S. Naval Reserve, "Diseases in the South Pacific with Special Reference to Diseases of the Tropics."

Personal.—Dr. Homer A. Sweetman, acting resident psychiatrist at the Malcolm A. Bliss Psychopathic Institute, St. Louis City Hospital, has been appointed superintendent of the St. Louis City Infirmary.—Dr. Paul J. Schrader has resigned as superintendent of State Hospital number 2 at St. Joseph.—Dr. Major G. Seelig, director of pathology at the Barnard Free Skin and Cancer Hospital, St. Louis, and professor of clinical surgery, Washington University School of Medicine, has been appointed a member of the Missouri State Cancer Commission by Governor Forrest C. Donnell.

State Survey Authorized to Determine Medical Education Needs.—The curators of the University of Missouri, Columbia, have approved a survey of the state's needs and resources for medical education preliminary to the establishment of a university policy regarding the institution's participation in medical education and conditions under which the program should be carried on, newspapers reported recently. The action, which has been under consideration by the board for several months, was formally approved at a meeting in St. Louis with the understanding that the study place special emphasis on the means, if any, through which graduates of the medical school may be induced to practice in the rural areas of Missouri. Newspapers stated that extent of the school's curriculum has been a particular problem since 1910, when the university dropped the final two or clinical years of medical instruction, requiring graduates of its medical school to transfer on their graduation with a bachelor's degree to some other institution for the final two years of instruction leading to the degree of doctor of medicine. In 1942 Kansas City alumni of the university proposed establishment of the clinical years of medical work at Kansas City, and the city offered use of its general hospital for the purpose. Recently the curators of the university withdrew their first approval of this plan. Members of the board of curators and of the medical school staff will conduct the survey. Medical schools to be visited will include those of the universities of Michigan, Ann Arbor, Virginia, Charlottesville, Wisconsin, Madison, and Tennessee, Memphis. The schools at Illinois, Chicago and Iowa City, have already been inspected as a part of the program. According to newspaper reports, among the subjects to be stressed in the survey is the future status of the two year medical school in the face of changing practices in medical instruction, which have made some authorities take the view that the two year plan is now obsolete, or the necessity for having the full four year course at the same site because of changes in instruction methods, and the financial commitments which would be involved in the maintenance of a full four year curriculum.

NEW YORK

Personal.—The Cortland County Board of Health is still seeking a successor for Dr. William E. Mosher Jr., Cortland, in order that he may be released for military service. Dr. Mosher, who had expected to enter military service, is still health commissioner in Cortland County. Dr. Bernard McD. Krug, New York, who was announced recently as the successor to Dr. Mosher, is unable to accept the appointment.

Submission of Malaria Specimens.—Effective January 1 the state sanitary code has been amended to require the submission of a thick film as well as a thin film when a diagnosis of malaria is considered, according to *Health News*. Both thick and thin films of blood on glass slides should be collected preferably between twelve and twenty-four hours after a chill (slide outfit). Stressing the importance of the manner in which the blood films are prepared, *Health News* has made available recommendations for the procedure.

Bequest Creates Professorship of Medicine.—The Edward C. Reifstein professorship of medicine will be set up at Syracuse University through a stipulation in the will of the late Horace White, formerly governor of New York. After establishing life trust funds of \$200,000 the will provides that three fourths of the residuary estate shall go to Cornell University at Ithaca and one fourth to Syracuse, the latter to be known as the Horace White Fund and the income to be used to pay the salary for the Reifstein professorship. The \$200,000 set up for life trusts will ultimately go to the two universities in their proportionate shares, *Science* reports.

New York City

Lois Miller Honored.—Mrs. Lois Mattox Miller, at a formal gathering of the Academy of Science in Havana, December 6, was made a commander of the Order of National Merit. Mrs. Miller, a member of the editorial staff of *Reader's Digest* and a writer on medical topics, was given the award in recognition of her work in the field of tropical medicine. She has also been made a life member in the Medical Society of Cuba.

Scientists Honored.—Duncan A. MacInnes, Ph.D., member of the Rockefeller Institute for Medical Research, was elected president of the New York Academy of Sciences at its annual meeting December 15. Life membership was awarded to Dr. Alexander Fleming, University of London, Sir Frederick Gowland Hopkins, University of Cambridge, Dr. Oswald T. Avery, Rockefeller Institute, Alfred L. Kroeber, Ph.D., director of the museum of anthropology, University of California, Berkeley, Arne V. Tiselius, biochemist of the University of Uppsala, Sweden, and T. Svedberg, head of the physical chemistry institute of the University of Uppsala.

Biologic Appointments to Research Laboratories.—Recent appointments to the staff of the biologic division of Food Research Laboratories, Long Island City, include Nathan Rakieten, Ph.D., formerly of the Laboratory of Applied Physiology, Yale University, New Haven, Conn., and lately first lieutenant in the U. S. Army Air Corps, and Roslyn T. Roth, Ph.D., formerly research microanalyst at New York University and more recently biochemist at New York Psychiatric Institute, Columbia Medical Center. Dr. Rakieten will supervise the animal laboratories, and Dr. Roth will specialize in the statistical aspects of the design and interpretation of bioassays.

TEXAS

Chamber of Commerce Controls Health Unit.—On October 7 a city ordinance was passed by the city council in San Antonio which places the control of the health unit under the direction of the local chamber of commerce. Nominations of the new board of seven members were to be made by the directors of the chamber of commerce, their terms to be two years. Physicians named to the new board are Drs. Patrick I. Nixon and Herbert J. Schattenberg.

Dr. Ewalt Named Acting Director of Psychopathic Hospital.—Dr. Jack R. Ewalt, associate professor of neuropsychiatry at the University of Texas Medical Branch, Galveston, and director of the electroencephalography unit of the John Sealy Hospital, has been appointed acting director of the Galveston State Psychopathic Hospital. The latter institution was closed in the summer by the state board of control on the basis that the buildings housing its operating staff had suffered storm damage.

New Appointments at Texas.—Charles M. Pomerat, Ph.D., professor of biology, University of Alabama, University, has been appointed professor of anatomy at the University of Texas Medical Branch, Galveston. R. W. Strandtmann, Columbus, Ohio, is now assistant professor of entomology in the department of preventive medicine and public health at the medical school. Ardell N. Taylor, Ph.D., formerly with the University of Texas, Austin, is now instructor in physiology at the medical branch and Dr. Jewell G. Hamrick, Dallas, instructor in pathology. George A. Emerson, Ph.D., associate professor of pharmacology, West Virginia University School of Medicine, Morgantown, has been named professor of pharmacology at the school.

VIRGINIA

Governor Challenges Physicians to Provide Lower Costs.—At a meeting of the Seaboard Medical Association in Richmond, December 2, a resolution was adopted to "take all possible steps to influence the enactment of laws for a more adequate distribution of medical and hospital care," the resolution to be sponsored by the medical profession of North Carolina and Virginia. To implement the program the association urged

the appointment of a special committee to confer with Governor Broughton of North Carolina and Governor Darden of Virginia for the purpose of suggesting and sponsoring such legislation as will be in keeping with the best traditions of the medical profession and serve the best interests of the public as a whole. The action followed the earlier warning of Governor Darden in an address in which he said that the federal government would get control of medicine unless physicians offered a better plan than the one now before congress.

Special Society Elections.—At recent meetings the following societies chose the officers indicated:

Virginia Obstetrical and Gynecological Society: Dr. Adrian L. Carson Jr., Richmond, president, Dr. Samuel E. Oglesby, Lynchburg, vice president and Dr. Lacy L. Shamburger, Richmond, secretary and treasurer.

Virginia Orthopedic Society: Dr. James B. Dalton, Richmond, president and Dr. James T. Tucker, Richmond, secretary.

Virginia Pediatric Society: Dr. Edwin A. Harper, Lynchburg, president, Dr. Robert B. Hightower, Alexandria, vice president and Dr. Emily Gardner, Richmond, secretary-treasurer.

Virginia Radiological Society: Dr. Clayton W. Eley, Norfolk, president, Dr. William P. Gilmer, Clifton Forge, vice president and Dr. Edward Latane Flanagan, Richmond, secretary-treasurer.

Virginia Urological Society: Dr. Thomas B. Washington, Richmond, president, Dr. Samuel A. Vest Jr., Charlottesville, vice president and Dr. Warren W. Koontz, Lynchburg, secretary-treasurer.

Virginia Section, American College of Physicians: Dr. Wyndham B. Blanton, Richmond, president and Dr. Alex F. Robertson Jr., Staunton, secretary-treasurer.

Dr. John Shelton Horsley, Richmond, was reelected president of the Virginia Cancer Foundation at its meeting in October. Dr. James R. Cash, Charlottesville, was named chairman of a committee on fellowship for cancer study.

WASHINGTON

Personal.—Dr. Percy S. Pelouze discussed gonorrhea before the Walla Walla Valley Medical Society, December 8.—Dr. Arthur L. Windom has resigned as superintendent of the King County Tuberculosis Hospital, Seattle.—Dr. Ralph L. Gregg, who concluded his internship at the King County Hospital, Seattle, January 1, has been appointed assistant superintendent of the hospital.

Hospital News.—It has been recommended that the Seattle City Hospital be abandoned and all city patients be treated at the King County Hospital, according to *Northwest Medicine*. The Public Safety Building, in which the city hospital is housed, is in poor condition and not suited for a modern hospital, it was stated. Clark General Hospital, Vancouver, was recently bequeathed \$100,000.

HAWAII

Territorial Election.—Dr. Douglas B. Bell, Honolulu, was chosen president of the Hawaii Territorial Medical Association during its annual meeting in May. Other officers are Dr. Arthur V. H. Molyneux, secretary and Dr. Stewart E. Doolittle, treasurer, both of Honolulu. Vice presidents are Drs. Leo L. Sexton, Hilo, Nathaniel M. Beniys, Honolulu, Samuel R. Wallis, Lihue, and Katsuyuki Izumi, Wailuku.

New Public Health Appointments.—Dr. Richard K. C. Lee, Honolulu, since 1937 deputy territorial commissioner of public health, in July became director of public health, a newly created position. Dr. Lee graduated at Tulane University of Louisiana School of Medicine, New Orleans, in 1933 and received the degree of doctor of public health at Yale University in 1938. The *Hawaii Medical Journal* says that Dr. Lee is the only physician in the territory who could have qualified for the position under the recently repealed law which fixed the educational and experience qualifications for the leading position in Hawaii's public health organization. He has at various times served as acting director of the bureaus of maternal and child health, communicable diseases and tuberculosis and as acting territorial commissioner of public health. He has lectured on public health administration at the University of Hawaii annually since 1937. He holds a reserve commission in the U. S. Public Health Service.—Dr. Charles L. Wilbar Jr., Honolulu, became president and executive officer of the Territory of Hawaii Board of Health, June 25, following his release from the army. Dr. Wilbar graduated at the University of Pennsylvania School of Medicine, Philadelphia, in 1932 and served his residency in medicine at the Queen's Hospital, Honolulu. After his two years service as director of the bureau of maternal and child health of the territorial board of health he was given a leave of absence to study postgraduate training in pediatrics in Cincinnati. He went into active army service on Dec. 13, 1941, serving first as captain and later as major. His army service included an assignment as health officer for the county of Maui.

GENERAL

Examination in Otolaryngology.—The American Board of Otolaryngology will hold its next examination at the Waldorf-Astoria, New York, June 1-4. The meeting that was tentatively scheduled to be held in Los Angeles in February 1944 has been canceled. Dr. Dean M. Lierle, University Hospitals, Iowa City, is the secretary-treasurer of the board.

Pediatric Board Reopens Group I.—The American Board of Pediatrics at its recent annual meeting decided to reopen group I, which requires that an applicant shall have been specializing in pediatrics for ten years or more. Group I will be kept open until July 1. All candidates regardless of training or length of time in practice must take both the written and the oral examinations.

Committee on Professional Relations.—On December 2, Pan American Health Day, the American Public Health Association announced the appointment of a committee on professional relations with Latin America under the chairmanship of Louis I. Dublin, Ph.D., third vice president and statistician of the Metropolitan Life Insurance Company, New York. Other members of the committee are:

Robert S. Breed, Ph.D., chief, division of bacteriology, New York Agricultural Experiment Station, Geneva, N. Y.

Gordon M. Fair, C.E., professor of sanitary engineering, Harvard University, Cambridge, Mass.

Dr. Henry E. Meleney, Herman M. Biggs professor of preventive medicine, New York University College of Medicine, New York.

Nathan Sinai, D.P.H., professor of hygiene and public health, University of Michigan, Ann Arbor, Mich.

Dr. Ernest L. Stebbins, commissioner of health of New York City.

Clair E. Turner, Dr.P.H., professor of biology and public health, Massachusetts Institute of Technology, Cambridge.

Grants for Research in Endocrinology.—Requests to the National Research Council Committee for Research in Endocrinology for aid during the fiscal period from July 1, 1944 to June 30, 1945 will be received until Feb. 28, 1944. Application blanks may be obtained by addressing the division of medical sciences, National Research Council, 2101 Constitution Avenue, Washington, D. C. In addition to a statement of the problem and research plan or program, the committee desires information regarding the proposed method of attack, the institutional support of the investigation and the uses to be made of the sum requested. No part of any grant may be used by the recipient institution for administrative expenses. Applications for aid of endocrine research on problems of sex the narrower sense cannot be given favorable consideration, but the committee will consider support of studies on the effects of sex hormones on nonsexual functions, for example on metabolism.

Fraudulent Representative of Manhattan Manufacturing Company.—The Manhattan Manufacturing Company of Chicago writes that an impostor has been soliciting orders in the name of the company, obtaining substantial deposits or full payments based on quick delivery or on unusually low prices. The name most frequently used is Mr. F. H. or A. H. Lancaster. The Manhattan Company states that every bona fide sales representative signs a bond application and that it does not now have nor ever had any one on its sales staff with this name or a similar one. The company states further that this impostor has sold bedding, towels, sheets and such items under its name even though it has never manufactured, handled, sold or had any catalogues illustrating such merchandise. The company suggests that a prospective purchaser observe that order books shown by the salesman contain the printed name of the company and that catalogues illustrate the indicated order bearing the same name as the order books. Customers should not pay any money on a blank form of an order on which the company's name is written by hand or rubber stamped. Instead the customer should offer to send the money directly to the company. The Manhattan Manufacturing Company regrets that this fraudulent representative has been mulcting the public and will appreciate any effort to apprehend him.

War-time Strains Responsible for Increased Death Rate.—The increased death rate in the population of the United States in ages over 50 years during the last twelve months is a result of the greater strains and the frequent exposures to disease that are a part of war-time life, according to the Bureau of the Census, U. S. Department of Commerce, Washington, commenting on a special study recently concluded. The fact that a large number of older persons have returned to a strenuous working life after years of retirement certainly has played a part in the increase, it was stated. From 1940 through 1942 the death rates by age and race in the United

States dropped gradually by amounts varying from 319 per cent to 11.1 per cent among the white and 5.9 per cent to 24.3 per cent among the nonwhite. In general the rates at the younger and older ages in both white and nonwhite declined more than the rates at the middle ages. However, when the returns from the bureau's 10 per cent mortality sample for the twelve month period ended September 1943 are compared with the final statistics for the calendar year 1942 it is seen that there have been significant increases in the white mortality at ages over 50 years. Every age group above that age has shown an increase, while at the ages below 50 the rates have remained practically stationary with the exception of the rate for ages under 5 years, which dropped 4.5 per cent in the period. The increases at the older ages ranged from 3.0 to 5.6 per cent. In the nonwhite group of the population the changes at ages over 50 years show a somewhat different pattern. Between 50 and 65 years and over 75 years the death rates increased, while between 65 and 75 they declined.

Sixth Annual Forum on Allergy.—The sixth annual forum on allergy will be held at the Statler Hotel, St. Louis, January 22-23. A feature of the meeting will be the presentation of the gold medal for outstanding contributions to clinical allergy to Dr. Robert A. Cooke, New York. Dr. Cooke will deliver the fourth annual forum lecture on "Observations on Allergic Reaction." Other speakers will include:

Roger P. Wodehouse, Ph.D., Yonkers, N. Y., Pollens in Hay Fever.

Dr. Edna S. Pennington, Nashville, Tenn., Allergy in the Older Housewife.

Dr. Alan G. Cazort, Little Rock, Ark., Critical Evaluation of Drugs Used in Treatment of Asthma.

Dr. Ethan A. Brown, Boston, Importance of Environmental Factors in the Management of the Allergic Patient.

Dr. Frederick W. Wittich, Minneapolis, Allergy to Fungi.

Dr. Milton B. Cohen, Cleveland, The Application of the Principles of Immunology to the Management of the Allergic Patient.

Dr. Elwood A. Sharp, Detroit, Endocrine Glands of the Allergic Patient.

Dr. Charles T. Eyermann, St. Louis, The Importance of Controlling During the Season of the Sensitization to Other Allergens: (a) Foods; (b) Other Inhalants.

Dr. Isidore S. Kahn, San Antonio, Texas, How Is the Specific Seasonal Treatment Best Carried Out?

Dr. William P. Garver, Cleveland, Is Perennial Treatment Superior to the Preseasonal Method of Treatment?

Dr. Carole B. Bohner, Indianapolis, What Is the Present Status of Oral Pollen Therapy?

Dr. Carliss M. Stroud, St. Louis, What Is the Optimum Dose of Pollen with Which to Approach the Season? Are Large Doses or Small Doses Advantageous Over the Moderately Sized Doses?

Dr. Abraham Colmes, Boston, Is There Any Advantage in Giving the Well Treated Patient Any Type of Pollen Therapy During the Season?

Dr. Samuel M. Feinberg, Chicago, What Is the Proper Specific Therapy in the Management of Pollen Asthma?

Dr. Karl D. Way, Akron, How Can We Avoid Constitutional Reactions?

Dr. Ralph G. Mills, Decatur, Ill., Is There Any Advantage in Giving Vitamins and Minerals as Supplemental Feedings or as Drugs During the Hay Fever Season to the Hay Fever Patient?

Dr. Armand E. Cohen, Louisville, Ky., Are Nose Drops Beneficial or Harmful? If Prescribed, Which Ones?

Dr. James Harvey Black, Dallas, What Seasonal Precautions on the Part of the Patient Are of Practical Importance in the Management of a Case of Hay Fever?

Dr. Albert Kuntz, St. Louis, The Autonomic Nervous System and the Allergic Patient.

Dr. Harry L. Alexander, St. Louis, Treatment of Intractable Asthma.

A series of study groups will be conducted Saturday with the following physicians in charge:

Dr. Theodore L. Squier, Milwaukee, Allergic Manifestations in the Blood.

Dr. Herbert J. Rinkel, Kansas City, Mo., Food Allergy.

Dr. Cecil M. Kohn, Kansas City, Mo., Physical Allergy.

Dr. Stephan Epstein, Marshfield, Wis., Specific Treatment of Contact Dermatitis.

Dr. Stanley F. Hampton, University City, Mo., Conduct of Allergy Clinics.

Dr. Theron G. Randolph, Ann Arbor, Mich., Lymphocytes in Relation to Allergy Anaphylaxis and Immunity.

Dr. Orval R. Withers, Kansas City, Mo., Allergic Headaches.

Dr. French K. Hansel, St. Louis, Allergic Coryza.

Dr. Karl D. Figley, Toledo, Ohio, The Clinical Management of House Dust Sensitivity.

Dr. Ralph Bowen, Houston, Texas, Food Allergy in Children.

Dr. Fannie Lou B. Lency, Oklahoma City, Management of Asthma in Children.

Dr. Carroll M. Pounders, Oklahoma City, Vasomotor Rhinitis in Children.

Dr. Bernard G. Efron, New Orleans, Allergy Manifestations Without Positive Skin Tests.

Dr. George E. Rockwell, Cincinnati, Chemical Nature and Standardization of Pollen Antigen.

Dr. Russell J. Blattner, St. Louis, "Sulfa" Drugs and Hypersensitivity.

On January 21 the Association of Allergists for Mycological Investigation will meet with Dr. Homer E. Prince, Houston, presiding.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Nov. 20, 1943.

Medical Education in German Prison Camps

The work of the War Organization of the British Red Cross Society for prisoners of war in Germany includes provision of parcels of food and clothing and, among other things, an educational books section which enables the younger men whose education or training has been arrested to employ their enforced leisure with some profit. Many institutions and colleges have provided books on almost every subject and also courses of lectures. A scheme by which the prisoners can take examinations has been adopted with the permission of British and German authorities. Most of the English universities cooperate in this. Medical students who are prisoners are well cared for and have an advantage over other groups in that the camp medical officer is available for coaching. Camp medical officers have been provided with appropriate textbooks and schedules for coaching men up to the standard of the first M.B. examination. In one camp the education officer has procured locally a number of cats, earthworms and other animals for dissection. Theoretical examinations actually take place, monitors being appointed in the usual way and the papers are returned to the examiners in England. However, it is not possible to hold examinations involving practical work. One enthusiastic group has asked for a complete human skeleton and a set of microscopic slides illustrating normal histology. These are being specially prepared.

Subjects allied to medicine, such as first aid and home nursing, are also included, principally for the benefit of nursing and medical orderlies in the camps. Standard Red Cross handbooks and wall charts have been sent. Examinations are held by the medical officers, who declare the result and issue temporary certificates. These will be exchanged for official forms after the war. Prisoners are working for examinations in chiropody, massage and medical gymnastics. It is hoped to arrange for certain blinded prisoners, already advanced in their study of the practical side of massage, to be permitted to take some part of their examination.

A great initial difficulty was the arrangement for a room which could be kept silent and undisturbed for study and examinations. Energetic camp education officers requested and eventually got what they wanted from the German authorities. As the interest of prisoners grew, it became obvious not only that an interesting way of employing enforced leisure had been found but also that it would help the men with plans for their immediate future on their return to civilian life. At the same time the awful period of mental stagnation complained of by so many prisoners after the last war, which took months or even years to get over, will be avoided.

War Difficulties of Medical Publications

The shortage of paper due to the war has produced government control of its use. Medical journals, like other periodicals, are restricted to about half their prewar size, although during a large part of the war period the publication of medical books was not seriously affected. Recently the difficulties have increased because of a shortage of labor as well as of paper. There are difficulties in the issue of new medical books and new editions. A big publishing firm, established over a hundred years, whose medical and dental books are known all over the world, complains that it is compelled to refuse overseas orders every week because of exhaustion of editions and because paper is unobtainable for reprints, even though the type is still stand-

ing. When the paper controller gives permission for the production of a new edition he sometimes restricts the number of copies, thus increasing the price at which they can be sold. The *Nursing Times* declares that the work in training schools for nurses is hampered by lack of essential textbooks. Publishers are restricted to a certain proportion of their prewar consumption. Such restriction does not exist for firms established during the war. The result is, important publishers complain, that they cannot produce valuable books because of paper restriction, while mushroom firms which have just sprung up can publish rubbish. No one may start a new periodical or open a new book shop without a permit, but any one can start a new publishing business.

The *British Medical Journal* complains that medical journals of the highest standing, already shrunk beyond recognition, were in 1942 compelled to choose between cutting down circulation and further cutting down pages. In the case of the *British Medical Journal* there was no alternative, because membership gives a right to a weekly copy and the number of members has risen by 6,000 since the outbreak of war to a total well over 44,000. The present supply of paper of the *Journal* is totally inadequate for the needs of the profession, and much valuable information is delayed at a time when quick diffusion of new ideas is of first importance. Lay newspapers have lately been allowed a better ration of paper, but medical journals have not.

The Benefits of Graduated Sun Bathing on a Troopship

The Army Medical Department *Bulletin* describes an experiment in graduated sun bathing recently carried out on board a troopship during an outward voyage through the tropics. Sun bathing parades were incorporated into the training program and the skin of every man was inspected by a medical officer before and after each parade. Care was taken to include all men employed below deck, such as orderly room clerks and mess waiters. During the first few days no man was allowed to expose himself to the sun except on these parades, and the wearing of helmets in the open was compulsory. On parade the front and back of the body and limbs were exposed for ten minutes on the first three days, for twenty minutes on the next three days, and then for half an hour daily for a week. After this, men who were tanned were allowed to sun bathe independently during the evening. At the end of three weeks, when most of the parades were discontinued, the men were not allowed to wear more than shorts all day, and helmets were no longer compulsory.

Special attention was paid to any deviation from normal reaction. Men with slight erythema were excused from parade for one day; those with severe erythema were excused for three days. Those who tanned unusually slowly were grouped in a separate parade under a medical officer. It was found that few men seemed to be hypersensitive to the actinic rays of the sun and that exposure was inadvisable for men with seborrheic dermatitis. Men with blond skin required extra care.

The author of the experiment, the senior medical officer of the troopship reports the following satisfactory results: (1) improvement in general health (average daily sick parade 1.5 per cent), (2) diminution of such skin disorders as impetigo, acne, scabies, tinea pedis and prickly heat, (3) low incidence of sunburn (2 cases) and of heat stroke (none), (4) relief of heavy strain on laundry facilities and (5) accelerated rate of acclimatization on arrival in a tropical country. The officer commanding the troops, in a warm tribute, states that on landing in India the men were sufficiently inured to the sun to take the field at once, while returning troops, some of whom had been in India eight years, were white of skin, sensitive to the sun and unable to work on deck without shirts and helmets. He concludes "The results of this valuable experiment admit of no argument."

BUENOS AIRES*(From Our Regular Correspondent)*

Nov. 1, 1943.

Medical Congresses

The second Inter-American Congress of Surgery and fifteenth Argentine Congress of Surgery took place in Buenos Aires October 11 to 15 with Dr. Oscar Capello presiding. There were fifty delegates from Pan American countries. Dr. Leo Eloesser of San Francisco was the delegate from the United States. The official topics were "Sulfonamide Therapy in Surgery," "Fractures of the Legs" and "Hyperthyroidism." Drs. Augusto A. Covaro, Enrique Lagomarsino, José Alberto Caeiro and Alejandro Ceballos, all of Buenos Aires, were official speakers. Dr. Lagomarsino based his article on personal observations of 1,143 fractures. He made special reference to the treatment of fractures, either closed or open and with or without complications. Special attention was directed to prevention and early therapy of gas gangrene and osteomyelitis in fractures. There were several sections on surgery, technical demonstrations of proctologic surgery and various specialties and a film on hydatidosis.

The first Inter-American Congress of Radiology was recently held in Buenos Aires. Dr. José F. Merlo Gómez presided.

Delegates to the congress resolved (1) to create an Inter-American College of Roentgenology in Buenos Aires, (2) to stimulate the creation of laws in Pan American countries to promote roentgenology and protect roentgenologists and (3) to provide for retirement of roentgenologists if they become victims of the practice of roentgenology.

At the close of the congress a monument in honor of Roentgen, Curie and the victims of roentgenology was unveiled in the Instituto Municipal de Radiología y Fisioterapia of Buenos Aires.

The fifth Argentine Congress of Obstetrics and Gynecology was recently held at the Faculty of Medicine of Buenos Aires. Dr. Frank R. Pasman was the president. The topics discussed were "Clinical Course and Treatment of Endometriosis," "Obstetric Endocrinology," "Treatment of Acute Puerperal Infection" and "Genital-Hypoplasia."

Medical Week

The first Medical Week on the History of Medicine was recently held at the Instituto de Historia de la Medicina of the Faculty of Medicine of Buenos Aires. Dr. Juan Ramón Beltrán was the president. The following speakers gave lectures and read papers on official topics: Angel H. Roffo, Buenos Aires, "History of Cancerology"; Dardo Corvalan Mendilaharsu, Buenos Aires, "The Faculty of Medicine of Buenos Aires in the Epoc of Rosas"; Leo Eloesser, San Francisco, "Pirate and Buccancer Surgeons"; Martín J. Becerra, Buenos Aires, "Edward Wilde's Generation"; Enrique de Gandia, Buenos Aires, "Origin of Syphilis in America"; Nicanor Palacios Costa, Buenos Aires, "Life and Work of Cosme Argerich"; Pablo Osvaldo Wolff, Buenos Aires, "Historical Aspect of Pharmacology," and José Arce, Buenos Aires, "Alejandro Posadas and His Work." There was also a special session on the history of pharmacy.

Poliomyelitis in 1942

The statistics of the Epidemiologic Department of the National Department of Hygiene show the following cases of poliomyelitis during the epidemic between October and December 1942: October 1 to 15, 4 cases; October 16 to 31, 11 cases; November 1 to 15, 38 cases; November 16 to 30, 117 cases; December 1 to 15, 146 cases, and December 16 to 31, 105 cases. There was a total of 421 patients in the period of three months; there were 406 cases among infants and 15 in children, adolescents and young adults. Two hundred and nine patients were boys and 196 were girls.

New Department of Public Health

A new National Department of Public Health and Social Assistance was created recently here. It includes the National Department of Hygiene, the Advisory Committee of Regional Hospitals, the National Institute of Nutrition, the Society of Beneficence of the Federal Capital, the National Centers of Social Assistance, the Department of Subsidies and all the national branches of the departments of Public Health and Hygiene. Dr. Eugenio A. Galli, mayor surgeon, R. A., was appointed president of the department. An honorary committee is carrying on some work looking toward incorporation in the new department of certain centers which are now branches of government departments. Dr. Galli suggested arrangements to give the benefits of social insurance to all Argentines.

Syphilis

Dr. Francisco Gerardo Russo is the head of a large venereal disease dispensary in Buenos Aires. He says that syphilologists have found that syphilis has increased recently. One hundred and thirty-one cases of primary syphilis and 99 cases of secondary syphilis were reported to the National Department of Public Health between January and September 1942, and 205 cases of primary syphilis and 130 cases of secondary syphilis were reported for the same period of 1943. Syphilis diminished greatly for the years 1939 and 1940 after establishment of venereal disease laws. Dr. Russo believes that the fulfillment of these laws demands strict supervision.

Brief News

The Argentine Congress of Medicine and the Pan American Week on Neuropsychiatry for 1944 were postponed. The "Dr. Rafael A. Bullrich Prize" was recently established with a fund of \$10,000, which was donated to the Academia Nacional de Medicina of Buenos Aires in homage to Dr. Bullrich, professor of clinical medicine of the Faculty of Medicine of Buenos Aires, who recently retired. The prize will consist of a gold medal, a diploma and a \$600 award. It will be given every two years for the best article on cardiology published during the two year period.

A donation of \$25,000 was recently given the Sociedad de Beneficencia of Buenos Aires for the construction of a pavilion for convalescents in one of the hospitals of the society.

The Hospital del Barrio Obrero was recently opened in Asunción, Paraguay. It was constructed with the cooperation of the Inter-American Service of Public Health.

The government of the United States offered a donation of \$500,000 to Uruguay for improvements in public health. The offering was made through Dr. John D. Long of the Pan American Sanitary Bureau of Washington, who recently visited Uruguay. Uruguay will contribute an additional fund of \$100,000 for the same purpose. The work on sanitation and public health in Uruguay will be carried on by American and Uruguayan specialized technicians.

Dr. Gonzalo Bosch was recently appointed regular professor of psychiatry of the Faculty of Medicine of Buenos Aires.

Marriages

HERMAN LAMAR SINGLETARY, Lake City, S. C., to Miss Martha Ann Newman of Charleston at Kingstree November 5.

MANNING LIONEL NELSON JR., North, S. C., to Miss Annie Elizabeth Howell of Ridgeway at Carlisle, Pa., August 14.

RICHARD COFFMAN SHRUM, Dayton, Va., to Miss Vennie Maurcen Parrott of Florence in New York November 6.

JOHN SCOTT SHAFFER, Wytheville, Va., to Miss Amanda Elizabeth McKnelly at Petersburg October 23.

GEORGE L. LESLIE, Howell, Mich., to Miss Hazel Wood of Pontiac, Mich., in Carlisle, Pa., November 5.

Deaths

Ambrose Francis Dowd, Newark, N. J.; University of Vermont College of Medicine, Burlington, 1910; member of the Medical Society of New Jersey, American Psychiatric Association and the National Committee for Mental Hygiene; served as president of the New Jersey Neuropsychiatric Association; served overseas in the neuropsychiatric division, medical corps, U. S. Army, during World War I; chairman of the medical advisory board of the Selective Service System; for many years member of the state board and department of institutions and agencies of control; consultant at the Irvington General Hospital, Irvington, St. Mary's Hospital, Orange, and the Presbyterian Hospital; on the staffs of the St. Michael's Hospital, St. James Hospital, Hospital and Home for Crippled Children and the American Legion Memorial Hospital; for two terms president of the medical staff of Hospital of St. Barnabas and for Women and Children; at one time medical director of the Newark City Hospital; died November 16, aged 56, of gastric ulcer.

George Franklin Shiels, Redwood City, Calif.; University of Edinburgh Faculty of Medicine, L.R.C.P. and L.R.C.S., Edinburgh, 1884; F.R.C.S., Edinburgh, Scotland, 1888; lecturer on medical jurisprudence, University of California, San Francisco, from 1890 to 1892 and professor of surgery from 1892 to 1898; professor of clinical surgery in the postgraduate department of the University of California from 1894 to 1898; assistant lecturer on surgery at the New York Polyclinic Medical School and Hospital from 1904 to 1906; professor of surgery at the Fordham University School of Medicine, New York, from 1905 to 1907; fellow of the American College of Surgeons; received medals and citations "for distinguished gallantry in action" during the Spanish-American War, the Philippine Insurrection and World War I; died in Palo Alto October 26, aged 80, of pneumonia.

Roy Parsons Forbes Ⓢ Denver; Western Reserve University School of Medicine, Cleveland, 1915; associate professor of pediatrics at the University of Colorado School of Medicine; specialist certified by the American Board of Pediatrics, Inc.; member of the House of Delegates of the American Medical Association in 1931; past president of the Denver Public Health Council; formerly vice president of the Denver Tuberculosis Society and the Colorado Tuberculosis Association; member of the American Academy of Pediatrics; a captain in the medical corps of the U. S. Army during World War I; served on the staffs of the Children's Hospital, National Jewish Hospital and St. Anthony's Hospital; author of "Health Record for Children"; died November 8, aged 55, of cerebral hemorrhage, hypertension and chronic nephritis.

Frank Hall Washburn Ⓢ Holden, Mass.; Tufts College Medical School, Boston, 1899; member of the American Society of Regional Anesthesia, Inc., American Urological Association, American College of Chest Physicians and the New England Roentgen Ray Society; fellow of the American College of Surgeons; chief of staff, Holden District Hospital, thoracic surgeon, Worcester County Sanatorium, Worcester, consulting surgeon, Rutland State Sanatorium, Rutland, and consultant in surgery and urology, Veterans Administration Facility, Rutland Heights; in 1931 delivered the George Washington Gay lecture at his alma mater; died in the New England Baptist Hospital, Boston, November 10, aged 72, of acute ileitis.

Willard John Stone Ⓢ Pasadena, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901; member of the House of Delegates of the American Medical Association in 1918; member of the American Society for Clinical Investigation; fellow of the American College of Physicians; clinical professor of medicine at the University of Southern California School of Medicine, Los Angeles; served as a major in the medical corps of the U. S. Army during World War I; on the staff of the Huntington Memorial Hospital; author of "Bright's Disease and Arterial Hypertension"; died October 30, aged 66, of coronary thrombosis.

Young Wilhoite Haley, Nashville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1897; member of the Tennessee State Medical Association; formerly professor of physiology and professor of materia medica and therapeutics in the dental department of Vanderbilt University; at one time chairman of the governing board of the Nashville General Hospital; formerly a member of the state examining board for nurses; for many years on the staff of St. Thomas Hospital; one of the founders and charter member of Protestant Hospital; died in Monteagle, Tenn., October 31, aged 69, of cerebral hemorrhage.

Allan Blanchard Stewart, Owatonna, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1891; member of the Minnesota State Medical Association; at one time mayor; fellow of the American College of Surgeons; served during World War I; major, medical reserve corps, U. S. Army, not on active duty; for many years physician and surgeon for the Minnesota state public schools; on the staff of the Owatonna City Hospital; died in St. Mary's Hospital, Rochester, October 31, aged 80, of heart block and chronic nephritis.

John Samuel Abney, Jackson, Miss.; Memphis (Tenn.) Hospital Medical College, 1905; died November 27, aged 67, of acute dilatation of the heart.

John Calvin Anderson Ⓢ Pittsburgh; University of Pittsburgh School of Medicine, 1913; specialist certified by the American Board of Otolaryngology; chief, nose and throat department, Columbia Hospital, Wilkesburg; died in the Allegheny General Hospital November 13, aged 60, of bronchogenic carcinoma of the right lung with metastases to the cerebellum and pons.

Vandiver L. Bell, Grand Rapids, Mich.; Eclectic Medical Institute, Cincinnati, 1907; died November 20, aged 70, of heart disease.

Alexander J. Berger, Arkansas City, Kan.; Milwaukee Medical College, 1906; member of the Kansas Medical Society; served during World War I; on the staff of the State Hospital for Epileptics, Parsons; died November 2, aged 59, of carcinoma.

Charles Delos Bo Dine Ⓢ Portland, Ore.; Northwestern University Medical School, Chicago, 1902; formerly assistant clinical professor of surgery at the University of Oregon Medical School; fellow of the American College of Surgeons; served during World War I; on the staff of the Emanuel Hospital, where he died October 18, aged 70, of injuries received in an automobile accident.

William Riley Brady, Seattle; University of Colorado School of Medicine, Denver, 1912; served during World War I; died in the Swedish Hospital, November 7, aged 59, of injuries received in an automobile accident.

Albert Franklin Brockman, Seattle; American Medical College, St. Louis, 1890; died October 10, aged 75, of coronary thrombosis.

George Spurgeon Bullock, Washington, D. C.; Meharry Medical College, Nashville, Tenn., 1938; died November 21, aged 31, in an automobile accident.

James Brandon Campbell Ⓢ Big Rapids, Mich.; Saginaw Valley Medical College, Saginaw, 1900; past president of the Mecosta-Oshtemo Counties Medical Society; formerly city commissioner, mayor and member of the board of supervisors; served as a captain in the medical corps of the U. S. Army during World War I; a trustee of the Ferris Institute for many years; on the staff of the Community Hospital; local surgeon for the Pennsylvania Railroad; a director of Citizens State Bank; died November 13, aged 69, of coronary occlusion.

Samuel Davidson Carrigan, Sandoval, Ill.; St. Louis University School of Medicine, 1905; member of the Illinois State Medical Society; served as coroner of Marion County; died in St. Mary's Hospital, Centralia, November 12, aged 61, of cerebral hemorrhage.

Harry Ray Carson, Phoenix, Ariz.; Northwestern University Medical School, Chicago, 1909; specialist certified by the American Board of Pediatrics, Inc.; member of the Arizona State Medical Association, American Society of Anesthetists, Inc., and the American Academy of Pediatrics; served on the staffs of St. Joseph's and Good Samaritan hospitals; died November 8, aged 58, of hypertensive heart disease.

Marshall Grant Clancy, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; served as police department surgeon; died November 28, aged 75, of heart disease.

John Marvin Davis, Red Bank, N. J.; University of the City of New York Medical Department, New York, 1887; for many years surgeon for the Furness Bermuda Steamship Line; died November 20, aged 77, of coronary disease.

Daniel Lee Dean, Hardinsburg, Ind.; Hospital College of Medicine, Louisville, Ky., 1903; died in Madison November 4, aged 78, of cerebral hemorrhage.

Richard L. Figgins, New Orleans; New Orleans University Medical College, 1907; died November 10, aged 53, of hemorrhage and shock from a self-inflicted gunshot wound.

Julius Mansfield Foster ⊕ Valley Stream, N. Y.; Long Island College Hospital, Brooklyn, 1899; school physician; one of the founders and vice president of the Valley Stream National Bank; died suddenly November 15, aged 68, of heart disease.

William Arthur Henderson, Kansas City, Mo.; Missouri Medical College, St. Louis, 1888; died November 18, aged 86, of cardiovascular disease and hypertension.

Alexander Ayer Higgs, San Diego, Calif.; Eclectic Medical Institute, Cincinnati, 1896; member of the House of Delegates of the American Medical Association in 1911; died September 10, aged 73, of cerebral hemorrhage and arteriosclerosis.

Pierre C. Hoag, Schenectady, N. Y.; Albany Medical College, 1878; died in the Ellis Hospital October 29, aged 90, of carcinoma of the prostate, hypertrophy of the prostate, uremia and chronic interstitial nephritis.

Adam Kemble ⊕ Washington, D. C.; George Washington University School of Medicine, Washington, 1905; member of the American Urological Association; also a pharmacist; served during World War I; a member of the board of regents of the Sibley Hospital; died in Mount Carmel, Pa., November 12, aged 65, of carcinoma.

Harry E. Thomas Kemper ⊕ Elizabeth, N. J.; Georgetown University School of Medicine, Washington, D. C., 1928; medical consultant on compensation court matters in the state; on the staffs of St. Elizabeth's Hospital and the Alexian Brothers Hospital, where he died October 18, aged 38, of coronary thrombosis and pulmonary embolism.

Gustavus A. Lusk, Ripley, Tenn.; Vanderbilt University School of Medicine, Nashville, 1881; died October 20, aged 88, of shock from a fractured hip.

Ernest Everest Martin, Allen, Ky.; University of Louisville School of Medicine, 1925; on the staff of the Martin General Hospital, Martin; died October 21, aged 43, of a fractured skull received in a fall.

Thomas Addison McCann, Dayton, Ohio; Hahnemann Medical College and Hospital of Philadelphia, 1891; formerly a member and president of the Ohio State Medical Board; for many years chief of staff, Miami Valley Hospital; died November 7, aged 84, of carcinoma of the prostate.

George Sheppard Moore, Nashville, Tenn.; Northwestern University Medical School, Chicago, 1910; clinical director of the Veterans Administration Facility, Tuskegee, Ala., from 1924 to 1937; died in the George W. Hubbard Hospital of Meharry Medical College October 28, aged 60, of acute peritonitis due to peptic ulcer.

Charles Francis Morris, Oteen, N. C.; Indiana University School of Medicine, Indianapolis, 1909; served during World War I; on the staff of the Veterans Administration Facility; died in an Asheville hospital October 30, aged 60, of injuries received in an automobile accident.

Lewis Burrows Morton ⊕ Los Angeles; State University of Iowa College of Medicine, Iowa City, 1901; specialist certified by the American Board of Surgery; member of the Western Surgical Association and the Pacific Coast Surgical Association; fellow of the American College of Surgeons; served as president of the staff and for many years a member of the surgical staff of St. Vincent's Hospital; died October 19, aged 65, of carcinoma of the sigmoid colon with metastases to the liver.

John Francis Nelson, New York; Columbia University College of Physicians and Surgeons, New York, 1905; assistant clinical professor of surgery at the New York University College of Medicine; member of the Medical Society of the State of New York; died September 30, aged 62, of heart disease.

Harry G. Nickel, Boiling Springs, Pa.; Baltimore Medical College, 1898; member of the Medical Society of the State of Pennsylvania; on the associate staff of the Carlisle Hospital, Carlisle, where he died October 28, aged 70, of coronary occlusion.

George Washington Nihart, Petoskey, Mich.; Rush Medical College, Chicago, 1883; past president and secretary of the Emmet County Medical Society; at one time mayor of Mendon; for many years county coroner and city health officer; died October 16, aged 87, as the result of a fractured hip received in a fall.

Aloysius E. O'Flaherty, Los Angeles; Kansas City (Mo.) Medical College, 1898; on the staff of St. John's Hospital, Santa Monica, Calif.; at one time on the staff of the Soldiers' Home Hospital, Soldiers Home, Calif.; died October 7, aged 71, of intestinal obstruction.

Bert R. Parsons ⊕ Cortland, N. Y.; Eclectic Medical Institute, Cincinnati, 1899; treasurer of the Medical Society of the County of Cortland; chief of the obstetric service, Cortland County Hospital; died November 4, aged 71, of coronary occlusion.

William George Pullen, Corrigan, Texas; Memphis (Tenn.) Hospital Medical College, 1903; member of the State Medical Association of Texas; president of the Polk County Medical Society in 1931; served as health officer of Corrigan; a member of the Lions Club and a director of the Citizens State Bank; died recently, aged 75, of cerebral hemorrhage.

George D. Ruthven, Rochester, N. Y.; Trinity Medical College, Toronto, Ont., Canada, 1895; aged 74; died recently of bronchopneumonia.

William Alfred Shoemaker ⊕ St. Louis; University of Maryland School of Medicine, Baltimore, 1885; an Affiliate Fellow of the American Medical Association; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; formerly clinical professor of ophthalmology at the Washington University School of Medicine; consulting ophthalmologist, Evangelical Deaconess Hospital; died November 7, aged 83, of coronary thrombosis.

Lester Eugene Siemon, Cleveland; Cleveland University of Medicine and Surgery, 1896; formerly a member of the Ohio State Medical Board; at one time on the staff of the City Hospital; died in Tionesta, Pa., October 3, aged 75, of a self-inflicted bullet wound.

Frank Floyd Wagoner ⊕ Chicago; Rush Medical College, Chicago, 1925; on the staff of the Norwegian American Hospital, where he died November 3, aged 48, of heart disease.

DIED WHILE IN MILITARY SERVICE

Clarence Pennell Baxter, San Diego, Calif.; Tufts College Medical School, Boston, 1914; Army Medical School, 1917; member of the California Medical Association; commissioned a first lieutenant in the medical corps of the U. S. Army on Jan. 20, 1917 and promoted to the grade of major on March 28, 1918; honorably discharged on June 30, 1922; appointed a lieutenant colonel in the Officers' Reserve Corps on Jan. 12, 1925 and served as contract surgeon from September 1935 to January 1937; returned to active duty with the medical corps, Army of the United States, on Oct. 10, 1940 and assigned to the Canal Zone, where he died April 27, aged 52, of gangrene.

David Clithero, Los Angeles; College of Medical Evangelists, Loma Linda and Los Angeles, 1940; commissioned a first lieutenant, medical corps, Army of the United States, on Aug. 18, 1942; died in Clovis, N. M., August 22, aged 32.

Edmund Francis Corrigan, St. Paul; University of Minnesota Medical School, Minneapolis, 1940; served on the resident staff of the City of Detroit Receiving Hospital; commissioned a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on July 7, 1942; died in the U. S. Naval Hospital, Seattle, February 16, aged 27, of Hodgkin's disease.

Frederic Francis De Metrovich ⊕ Fowler, Colo.; University of Colorado School of Medicine, Denver, 1934; member of the Illinois State Medical Society; specialist certified by the American Board of Pediatrics, Inc.; formerly instructor in pediatrics at the Northwestern University Medical School and on the staff of the Children's Memorial Hospital, Chicago; captain, medical corps, Army of the United States; died in the Southwest Pacific area November 21, aged 35, of malaria.

Paul Churchill Johnson, Montoursville, Pa.; Jefferson Medical College of Philadelphia, 1940; member of the Medical Society of the State of Pennsylvania; commissioned a first lieutenant in the medical corps, Army of the United States, on Sept. 9, 1942; died in Hazard, Ky., August 14, aged 28, in an aircraft accident.

Bernard Jay Rike, Pueblo, Colo.; University of Colorado School of Medicine, Denver, 1939; commissioned a first lieutenant in the medical reserve corps, U. S. Army, on May 29, 1939 and promoted to captain on Nov. 22, 1942; died in the Southwest Pacific January 7, aged 29, of typhus.

Bureau of Investigation

DANGEROUS TO HEALTH

When Used as Directed

[EDITORIAL NOTE—These abstracts concern preparations which were specifically declared by the Food and Drug Administration of the Federal Security Agency to be dangerous when used in accordance with the directions given on the label by the manufacturer. The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment; (4) the composition; (5) the type of nostrum; (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment.]

Goodwin's Laxative Cold Tablets and No. 48511-C Tablets.—Shipped in February and March 1941 by Sharp & Dolme, Philadelphia, as No. 48511-C Tablets to Read Drug and Chemical Company, Baltimore, and repackaged by them as Goodwin's Laxative Cold Tablets. Composition in each tablet acetanilid (approximately 2 grains), quinine sulfate ($\frac{1}{4}$ grain), podophyllin, capsicum and extract of belladonna. Repackaged tablets misbranded because dangerous to health when used in dosage and with frequency and duration suggested in labeling, further misbranded because terms "Goodwin's Laxative Cold Tablets" and "Effective in the Treatment of Colds. Relieves the Feverish Conditions which Accompany Colds" and "Keeps the Bowels Active" gave false impression that product was an effective treatment for colds. Also misbranded because amount of belladonna alkaloids present was not properly declared on label. Again misbranded because label did not adequately warn against use by children or in those pathological conditions wherein it might be dangerous to health or caution against unsafe dosage and duration of administration, since label gave no warning that use should be discontinued if a skin rash appeared, or that tablets should be used cautiously if dryness of throat occurred; that they should be discontinued if rapid pulse or blurring of the vision resulted; that they should not be taken by children, that frequent or continued use might be dangerous to health by causing serious blood disturbances, anemia, collapse, or dependence on the drug; that the preparation should not be taken by elderly persons except on competent advice; that frequent use might lead to dependence on laxatives to move the bowels, and (in the case of the bulk tablets) labeling did not warn against use of these tablets in the presence of abdominal pain, nausea, vomiting or other symptoms of appendicitis.—[D. D. N. J., F. D. C. 659, February 1943]

Interferin.—Keefer Laboratories, Chicago. Shipped Nov. 3 and 27, 1941. Composition (expressed in percentages) essentially potassium soap (approximately 11.3), sodium soap (approximately 12.5), potassium iodide (approximately 6), benzoic acid (0.4), fats and/or oils (0.4), alcohol and water. Adulterated because quality fell below that purported, since product was offered for use by injection into the uterus, thereby implying that it was sterile, whereas it was contaminated with viable bacteria of a disease-producing type. Misbranded because dangerous to health when used in dosage and with frequency and duration suggested in leaflet accompanying carton, as an abortifacient. Further misbranded because of label representation that product had proved its value in more than 5,000 cases without a single known fatality, that it had been developed after extensive research, offered very definite advantages over old methods and was efficacious and appropriate for several ovarian complications, as well as syphilis, blood, skin, kidney and cardiac ailments and tuberculosis of the lungs, endocrine disorders, organic and functional nervous system diseases, blindness and other eye conditions, ear troubles, caries, hereditary diseases such as insanity and epilepsy, and some other things.—[D. D. N. J., F. D. C. 657, February 1943]

Lambert's Powders.—Stanley Drug Company, Minneapolis. Shipped July 19, 1940. Composition: each powder contained $2\frac{1}{2}$ grains of acetanilid and salol, and 5 grains of aspirin. Misbranded because dangerous to health when used in the dosage or with the frequency or duration recommended in the labeling. Further misbranded because labeling failed to bear adequate warning that giving the product to children might be dangerous to health, or caution against unsafe dosage or methods or duration of administration, since labeling did not warn that frequent or continuous use of a product containing $2\frac{1}{2}$ grains of acetanilid per powder might cause serious blood disturbances, anemia, collapse, or a dependence on the drug. Further misbranded because statement on carton, "muscular aches and body pains, lumbago" was false and misleading, since it represented that the drug was efficacious in the treatment of such conditions, whereas it was not.—[D. D. N. J., F. D. C. 702, April 1943]

Voltamp Battery No. 7.—Voltamp Electric Manufacturing Company, Baltimore. Shipped April 25, 1941. A device containing batteries, an electric coil, and attachments for applying electric current to the body. Misbranded because dangerous to health when used with frequency or duration suggested in labeling for a long list of disorders, including aphasia, apoplexy, Bell's palsy, bladder paralysis, blindness, catalepsy, muscular cramps, poliomyelitis, tetanus, spinal meningitis, neuritis, baldness, cataract, menstrual troubles, anemia, dropsy, cystitis, corns, Bright's disease, St. Vitus' dance, diabetes, diphtheria, exophthalmic goiter, obesity, tonsillitis and varicose veins, that it would increase the supply of mother's milk, remove superfluous hair, rid the skin of blemishes, develop the bust and other shrunken parts, and permanently relieve constipation.—[D. D. N. J., F. D. C. 658, February 1943]

Correspondence

THE 9-9-9 PLAN FOR INTERNSHIPS AND RESIDENCIES

To the Editor:—The medical services of the Army and Navy are justly proud of the superb health record of our armed forces and of the even more remarkably low mortality rate in wounded soldiers and sailors. Part of this magnificent performance is due, of course, to the efficient organization of the medical services of the armed forces. A large share has resulted from the advances in medical knowledge of the past twenty-five years. It seems probable, however, that the major element in the achievements of the military medical services is the high standard of medical education in this country during the past quarter century. The doctors now serving the nation in a military capacity are almost all graduates of modern schools and many have had excellent opportunities for postgraduate education. Unless the men coming into active service know the fundamental principles of medicine, have been taught to keep abreast of advancing knowledge and by arduous and prolonged training have learned the application of their knowledge, the great advances in medicine and excellent organization cannot produce the efficient medical service which is being given to our armed forces at the present time.

The Army, the Navy and the country itself owe a large debt to the medical educators of the past twenty-five years, and particularly to those educators who have served on the Council on Medical Education and Hospitals of the American Medical Association. It is therefore disturbing to find that the Council has given its support to the promulgation of the so-called 9-9-9 plan for hospital internships and residencies. This action appeals to many medical educators as a real disservice to the armed forces. An opinion so diametrically opposed to that of the general staffs of the Army and Navy should not be expressed without good reasons.

In contrast to the finely trained personnel of the present armed services, it will not be long before the medical schools and hospitals are delivering to the Army and Navy men of a different stamp. They will be medical graduates who have seen nothing but hurried, incomplete, perhaps even at times ill advised medical service. A competent resident staff is not only a matter of numbers. There are also involved matters of training and experience. A resident of but eighteen months of training can in no sense set the example that a resident of three to five years of previous experience can set. Nor can he teach. Without adequate resident staffs, accurate and complete histories and physical examinations, close and careful observation of patients, conscientious supervision of student progress and the example of technical procedures carried out by men who know how cannot be preserved. The elaborate rituals of present day medicine are designed for the safety of the patient; but a second purpose of equal if not greater importance in teaching hospitals is to demonstrate to the medical student work well done. Without trained assistants in adequate numbers the good precepts of the classrooms will be more than offset by the much more impressive but unavoidable bad practice at the bedside. The frantically busy teacher cannot add to his increasing burden the task once borne by the thoroughly trained resident of teaching the student the details of patient care.

We are not alone in the conviction that undergraduates educated under the 9-9-9 program cannot be anything but poorly trained doctors with no real background for medical growth through the years. When the Army and the Navy get these men who have not been exposed to good example and for whom there has been no time for reflection, contemplation, reading, maturing, how long will the splendid military medical record stand? If this war ends shortly, much harm will be done, and if the war lasts long the results will be irremediable.

There would be no purpose in such sentiments as these unless a feasible alternative course could be seen. This communication is written in the firm conviction that, for the sake of ultimate victory and an America worth saving, the quality of medical education should be given top priority among those peacetime traditions to be preserved; and medical education is now seriously threatened.

Let us inquire what gains the armed forces are making at such cost. On Jan. 1, 1944 a group of young physicians will become available from the teaching hospitals for military service. It is hard for the outsider to estimate how many of these there will be who would not otherwise then enter the Army or Navy. Since there are only seventy-seven medical schools in this country, and since only a minor though important part of the house staffs from the teaching hospitals is being prematurely released, an estimate of the immediate increment to the Army and Navy would be 500 men. Since hospitals generally have already pared their staffs to a low figure, the number might be less. Compare these figures with the present military medical roster of perhaps 50,000. The additional immediate strengthening of the military services is obviously proportionally minute, at the outside probably not more than 1 per cent. Furthermore, this is only an immediate gain. No greater number of men will be available on Jan. 1, 1945 and later than would have been available if the 9-9-9 plan had not been imposed on teaching hospitals.

The preservation of trained house staffs in the teaching hospitals would make possible a passable education for undergraduate students in spite of the accelerated program and would furnish from the house staffs a leaven of well trained men for replacement in the armed services. These two things alone would pay dividends to the Army and Navy beyond computation. It would seem an elementary proposition that these compensations would enormously outweigh the relatively insignificant immediate gains.

No doubt the Council on Medical Education has considered the propositions made herein and has made its decision on well grounded reasons. Many conscientious medical educators would like a frank presentation from the Council of those reasons.

If nothing can be done to improve the present situation, the medical profession can be assured that its teachers will endeavor to do the best job they can in spite of almost insuperable handicaps to good teaching.

[This statement was referred to the Council on Medical Education and Hospitals. The Council comments:]

To the Editor:—Every one interested in high standards of medical education and medical service both in the armed forces and in civilian practice shares with the correspondents their great concern over the wartime training of doctors. Curtailment of staff has multiplied the difficulties for remaining teachers. Uncertainty of the future has adversely affected student morale. A 30 per cent increase in annual medical school admissions and graduates has meant acceptance of some students whose qualifications may be open to question.

On purely educational grounds, it would be impossible to defend a nine month internship, which must be regarded as a wartime educational casualty. Reluctantly, and only after careful consideration of the advantages and disadvantages and weighing the possible alternatives, the Council has recognized the so-called 9-9-9 plan as the best available under present wartime conditions.

The plan conserves medical manpower for both military and civilian use. Each year approximately 7,000 men graduate from medical school under the accelerated program. Under the old plan, three months of their internships would overlap with the internships of the next class. The quality of instruction in the overlapping period was often inferior, adding considerably less than the equivalent of three months' time to the nine month non-overlapping period. On the other hand, under the 9-9-9 program about 3,000 of these men will be available three months early each year, or the equivalent of 750 physician-years annually. Seven hundred and fifty physicians represents the complement of medical officers for approximately 125,000 new troops.

The 9-9-9 program assures the deferment of assistant residents and residents, even though the period of additional training is less than the three or more years generally considered desirable, and readily attainable in peacetime.

The Council's opinion that the 9-9-9 program is the best that can be obtained under the circumstances is not "diametrically opposed to that of the general staffs of the Army and Navy." The 9-9-9 program was the only method of deferment of commissioned officers as assistant residents and residents on which agreement could be reached. If a one year internship was to be continued, hospitals would be forced to operate without any commissioned officers deferred as residents. It is better to have one third of the intern group continue for nine months as assistant residents and one sixth of the group for a second nine months as residents than to have no deferments for hospital service after the first year of internships. The latter was apparently the only alternative and was considered to be less desirable than the 9-9-9 program.

No one would differ with the educational principles pronounced by the correspondents. In wartime, educational standards must be preserved with but one qualification. There must also be a maximal contribution by medical education to winning the war. That contribution has already been and will continue to be of inestimable value, thanks to the efforts of teaching staffs operating under almost insurmountable difficulties.

REACTIONS AFTER SPINAL ANESTHESIA

To the Editor:—The editorial in THE JOURNAL, Oct. 9, 1943 entitled "Reactions After Spinal Puncture" interests me because of such reactions in connection with spinal anesthesia. These reactions, while rare of late years, after some considerable experience with spinal anesthesia are attributed by me primarily to an atraumatic puncture with a 20 gage spinal needle. The possible theories of the mechanism of these headaches is interesting but still largely academic.

Of only empirical value in their treatment but nonetheless immediate in alleviation of these headaches is the slow intravenous injection of 7½ grains (0.5 Gm.) of caffeine with sodium benzoate. One such injection results in complete cessation; rarely a second or third injection may be necessary at six hour intervals. There have never been any untoward reactions from this therapy in quite a number so treated for the past fifteen years.

This observation was reported by me some years ago in an article on spinal anesthesia published in the *American Journal of Obstetrics and Gynecology*. However, experience in the Army indicates that it is not generally known and was not mentioned in the editorial. I have inquired of several pharma-

cologists and physiologists as to the possible explanation of the action of caffeine with sodium benzoate without enlightenment.

An interesting companion article in this connection appears in the abstract section of the same issue of THE JOURNAL entitled "Caffeine Withdrawal Headaches," by Dreisbach and Pfeiffer (*J. Lab. & Clin. Med.* 28:1212 [July] 1943, abstr. THE JOURNAL, Oct. 9, 1943, p. 382).

HALL G. HOLDER, Lieutenant Colonel, M. C., A. U. S.

EMERGENCY MATERNAL AND INFANT CARE PLAN FOR WIVES AND CHILDREN OF ENLISTED MEN

To the Editor:—The widespread dissatisfaction with the management of the emergency maternal infant care plan for wives and babies of men in the armed forces by representatives of the Children's Bureau emphasizes the need for a committee, nationwide in scope and representation, to meet with government bureaus when they have to administer medical care programs. Could not the Council on Medical Service and Public Relations call together representatives of the various state medical societies and departments of public health to consider policies to be followed in the administration of such plans? Such a committee could offer its cooperation to the persons or bureau responsible for the administration of the program. If necessary, the committee could offer uniform nationwide opposition to ill considered schemes that might be put forward by the bureau. It would be difficult for any bureaucrat to ignore such a committee. Points of difference, if any arise, could be ironed out in friendly conference instead of by the present cumbersome plan of having each state fight its own battle without being too familiar with the feeling of the profession in other states. By offering such cooperation—and, if necessary, opposition—needlessly irksome regulations could be avoided. The profession could better protect the health and interests of those the law was designed to serve as well as its own interests. By the same maneuvers it could avoid the oft voiced criticism that the profession never offers anything but opposition to medical care programs.

BOARDS OF MEDICAL EXAMINERS BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, Dec. 25, page 1137.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* Jan. 17-19. *Part III.* Various centers, January. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Oral.* *Part II.* Chicago, June 12-16. Final date for filing application is March 12. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written,* Various large cities, May 8. *Oral.* Chicago, June 9-10. Final date for filing application is April 1. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Part II.* May or June. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6, Pa.

AMERICAN BOARD OF OPHTHALMOLOGY: Chicago, October. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Written and Oral.* *Part II.* Chicago, Jan. 21-22. Sec., Dr. Guy A. Caldwell, 3503 Prytania St., New Orleans, La.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Oral.* New York City, June 1-4. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City, Ia.

AMERICAN BOARD OF PEDIATRICS: *Written.* Locally, Feb. 4. *Oral.* Philadelphia, March 25-26, and San Francisco, May 6-7. Sec., Dr. C. A. Aldrich, 707 Fullerton Ave., Chicago.

AMERICAN BOARD OF SURGERY: *Written.* *Part I.* March 10. Final date for filing application is Jan. 1. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

AMERICAN BOARD OF UROLOGY: *Oral.* Chicago, Feb. 15-17. Sec., Dr. Gilbert J. Thomas, 1409 Willow St., Minneapolis.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Hospitals: Property of Not for Profit Corporation Operated for Benefit of Individual Physicians Not Exempt from Taxation.—A Wisconsin statute provides exemption from taxation with respect to the property of any benevolent association used exclusively for the purposes of such association and which is not leased or otherwise used for pecuniary profit (Wisconsin Stats., sec. 70.11 [4]). This statute, the Supreme Court of Wisconsin held in two recent cases, *Prairie du Chien Sanitarium Co., Inc. v. City of Prairie du Chien*, 7 N. W. (2d) 832 and *Riverview Hospital v. City of Tomahawk*, 11 N. W. (2d) 188, does not grant tax exemption to a nonprofit hospital corporation to which has been conveyed a hospital previously operated for profit, where the hospital under the new corporate setup is used primarily for the greater profit and convenience of the physician that built and originally owned the hospital even though the hospital accepts all patients who apply regardless of their ability to pay and operates at a deficit, which is made good by the physician referred to.

In the *Prairie du Chien Sanitarium* case the *Prairie du Chien Sanitarium Company, Inc.*, was a successor corporation to a private corporation for profit and had conveyed to it a hospital previously owned by the corporation for profit. The members of the new corporation were Dr. and Mrs. Satter, Dr. Dessloch, a layman who acted as the business manager of the hospital, and three relatives of the Satters, who paid nothing for their membership. Drs. Satter and Dessloch by agreement with the new corporation had the exclusive right to perform surgery in the hospital. These physicians received no salaries from the hospital but were provided without cost with heated, unfurnished offices in the hospital, rent free, and one meal a day. In return they supervised without compensation the hospital and its personnel. About 30 per cent of the total number of cases treated in the hospital were county and municipal patients whom the hospital cared for under contract for less than cost. These patients were treated by Drs. Satter and Dessloch without charge. The other patients in the hospital were private patients of the two physicians and other physicians, who were charged regular rates, though about 10 per cent of the total number of all accounts were not collected, apparently because of inability on the part of the hospital to collect. The hospital corporation contended that its property was exempt from local taxation in a suit it instituted against the city of *Prairie du Chien* to recover taxes paid under protest. The trial court dismissed the complaint, and the hospital appealed to the Supreme Court of Wisconsin.

In view of the statute referred to relating to tax exemption, said the Supreme Court of Wisconsin, for the hospital's contention to be sustained it must appear that (1) the hospital is a benevolent association (2) the personal property of which is used exclusively for the purposes of the association and (3) the real and personal property of which is not used for pecuniary profit. The court then discussed tests to be applied to determine what constitutes a hospital a benevolent association. It is clear, said the court, that the fact that the articles of incorporation provide that the institution is benevolent and charitable is not controlling. The actual financial setup of the hospital is important. If the books of the corporation show a substantial profit, this is a circumstance tending to negative the idea of a benevolent institution. The fact that the hospital receives and is dependent on donations indicates a benevolent character, as does the fact that it takes all patients who apply, regardless of their ability to pay, or at least that it does take a fair number of charity patients. A final and most important test is whether the members of the corporation render services without compensation. Obviously neither a single test nor isolated answers to each of the questions posed will automatically determine when

a hospital is a benevolent association. The facts of each case must be regarded as a whole, and the substance of the scheme of operation as it exists must be examined.

The Prairie du Chien Sanitarium operated for the fiscal year ended March 31, 1941 at a loss of about \$388. It received donations from the members of the corporation only. Such donations, said the court, do not make a hospital a benevolent association. *Rogers Memorial Sanitarium v. Summit*, 228 Wis. 507, 279 N. W. 623. In the present case the individual physicians were making from \$7,500 to \$10,000 a year. The manager, another member of the corporation, was paid a salary of \$140 a month. The hospital alleged that it took all patients who applied, but so far as the record shows, said the court, the 10 per cent of the patients whose accounts were not collected and who were classified as neither private nor county patients were billed for regular charges and everything was done to collect these bills. The chief point relied on by the hospital to establish the benevolent character was that the physicians in charge of the hospital were not paid any salaries for their services as medical directors of the hospital or for the operations they performed on county patients and those patients who came to the hospital without their own physicians. Whether it is exact, answered the Supreme Court, to say that these physicians received no compensation for their services is doubtful. They received their offices in the hospital rent free as well as the use of the hospital facilities and one meal a day. Whether or not the compensation was of value equivalent to the services rendered, it is clear that there is not a complete absence of remuneration such as is found in the cases in which all the work in the hospital except medical services is performed by the members of a religious order.

This leads us, continued the court, to the second and third points as to whether or not the property is used exclusively for the purposes of the hospital corporation and whether it is used for pecuniary profit. A corporation claiming to be benevolent to qualify its property for exemption from taxation must use it so free from connection with profits accruing to those owning it as clearly to be a charitable institution. Hence the personal property, grounds and buildings of a hospital are not exempt when members of the owner association are using the hospital as an adjunct to their private practice in such a way that it becomes a source of substantial help in the matter of earnings to be derived from the practice of their profession. It seems clear that even if we assume that the hospital is a benevolent association the property is used as much to advance the individual fortunes of the surgeons who manage it as it is for charitable purposes. There can be little doubt that the hospital is maintained primarily for the greater convenience and profit of these physicians in the practice of their profession. The physicians may, and under their management and control of the hospital did, give without recovering pay therefor of their time and skill in caring for people who did not pay for such care, but by reason of the use of the hospital in relation to their private practice the benefits extended were those of the physicians and not a contribution to public welfare by a benevolent association. The Supreme Court accordingly held that the property of the hospital was subject to local taxation.

As has been indicated, a similar result was also reached in the Riverview Hospital case. In that case Dr. Henderson established and operated a hospital in Tomahawk. Later for a nominal consideration he conveyed the hospital property to a corporation organized as a nonstock, nonprofit corporation. The members of the newly formed corporation were Dr. Henderson, his wife and Dr. MacFarlane, a dentist and a friend of Dr. Henderson. In the articles of incorporation of the new corporation it was provided that members of the corporation were to receive no dividends or any pecuniary profit, and all profits, if any, were to be used solely in increasing the facilities of the hospital and in the reduction of rates. The hospital received all persons applying for admission without first making inquiry as to their ability to pay. In 1940 it operated at a loss of around \$3,000, which was made good by Dr. Henderson. The hospital corporation instituted action against the city of Tomahawk to recover taxes paid on its property under protest, and from a

judgment in favor of the hospital corporation the city of Tomahawk appealed to the Supreme Court of Wisconsin, which held the hospital corporation liable for taxation on the broad grounds advanced in the Prairie du Chien case.

While the setup in the Riverview Hospital case, the Supreme Court pointed out, was somewhat different than in the Prairie du Chien case, still the surrounding circumstances showing purpose, management and connection with private enterprise was such that the hospital was under the rule recognized in the Prairie du Chien case that "an association or corporation claiming to be benevolent, in order to qualify its property for exemption from taxation, must use it so free from connection with profits accruing to those owning it as clearly to be a charitable institution." The property of a hospital corporation, said the court, is not exempt from taxation when members of the owner organization are using it as "an adjunct to their private business in such a way that it becomes a substantial help in the matter of earnings to be derived from the practice of their profession." All that was said in the Prairie du Chien case covering the use made of the hospital by its owner and his control over it appeared in the Riverview Hospital case although in the latter case the hospital did not specifically grant to Dr. Henderson exclusive use of the operating room and provide for meals. However that may be, there was no doubt that the hospital was conducted and managed primarily for the greater income and profit of Dr. Henderson in the practice of his profession. The evidence showed that Dr. Henderson, owing to differences arising between himself and the only other hospital in Tomahawk, was without hospital facilities and he organized the Riverview Hospital, giving it the property involved. A charge was made for every patient entering the hospital, and every means was used to effect collection. At the time the corporation was formed, it adopted the fees originally fixed by Dr. Henderson when operating the hospital as an individual. It appeared that all deficits of the hospital were paid for by him. It also appeared from the incorporation proceedings that the organization was so arranged that the power to control the property was in Dr. Henderson. The control was not given irrevocably as a charity to a charitable or benevolent institution. The benefit conferred by the organization of the hospital, the court held, could not be said to be so much to the public and so little to the donor and corporate owners as to place it in the class of property covered by the tax exemption statute. It is not unusual, said the court, for professional men to fail in collecting a just fee for some of their effort. A profession is based on an ideal which comprehends service to mankind. While the loser may find solace in the thought that by reason of a patient's failure to pay his bill a contribution to charity has been made, the kindness granted cannot become a justification for exemption from taxation on the hospital in which the service was rendered. Accordingly, as in the Prairie du Chien case, the Supreme Court held that the Riverview Hospital corporation was subject to local taxation.—*Prairie du Chien Sanitarium Co., Inc. v. City of Prairie du Chien*, 7 N. W. (2d) 832 (Wis., 1943); *Riverview Hospital v. City of Tomahawk*, 11 N. W. (2d) 188 (Wis., 1943).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Plastic Material in Medicine: Preliminary Report on Use of Lucite and Nylon Fabric in Orthopedic Surgery. M. S. Burman.—p. 124.

Cranio cerebral Wounds: Exteriorization Method of Treatment.—Browder has been applying for several years a method for neglected wounds of the brain which is patterned after the plan of exteriorization of brain abscess as recommended by King. This method prevents the formation of fungus cerebri. The scalp, bone, dura and brain are debrided and all softened cerebral tissue is removed by suction, hemostasis being secured by applying the electrocoagulating current to the metal tube of the sucker whenever a blood vessel is drawn into it. The dura should be cut away to the limits of the cerebral defect. After débridement, cerebrospinal fluid should be withdrawn through the spinal needle in order to reduce the possibility of cerebral herniation. After the cerebral cavity has been opened widely, the entire area is covered with a single layer handkerchief of mesh gauze (44 by 40 per square inch). Sulfanilamide crystals are blown on to the handkerchief lining the cavity. The cavity is then packed with $\frac{1}{2}$ inch gauze strips to the level of the scalp. The flaps of scalp are brought over the area and loosely approximated. A snug fitting dressing composed of wet, flat gauze held firmly in place by a skull cap should be applied to prevent herniation. The wound is not dressed for three to

five days. For dressing the patient is placed on his side, cerebrospinal fluid is withdrawn from the lumbar thecal sac, the wound is reopened and the gauze pack is removed. The cavity lined with the adherent gauze handkerchief is filled with full strength hydrogen peroxide and washed out with saline solution. This should be repeated three or four times before an attempt is made to loosen the handkerchief. The removal of the lining gauze at the first dressing is a slow and tedious procedure, but each dressing becomes less arduous. In about ten to twelve days the entire cavity is covered with granulation tissue, the surface of which must not be injured during dressings. Slowly the cerebral wound becomes smaller and finally, by gradual decrease in the amount of intracranial packing, the granulating surface rises to the level of the cranial vault. After epithelization becomes complete, plastic repair of the scalp and cranial defect may be carried out at a later date.

Sex Hormones in Post-Traumatic Psychosis in the Aged.—Cogswell and Davis point out that not infrequently a senile person placed in bed to recover after some form of trauma, often trivial, breaks down mentally or physically and dies. Many of these patients appear to be in excellent condition up to the time of their injury. Getting these people out of bed as soon as possible and allowing them to exercise is of value in preventing this syndrome. In many cases this cannot be allowed, owing to the nature of the patient's injury. The authors report that 3 patients showed mental symptoms following injuries confining them to bed. Because such mental symptoms were not seen in younger patients under similar conditions, gonadotropic substance was given, and the mental symptoms have disappeared.

Nerve Transplantation.—Propper-Grashchenkov discusses experiments on replacing defects in peripheral nerves, in particular the Ignatov method of utilizing human nerves taken from corpses and treated with solution of formaldehyde. Ignatov used corresponding nerves, so that the diameter of the nerves could be matched. During the Finnish war there were 13 cases of transplantation in which the defects were so large that direct contact of the severed nerves was impossible. One sciatic nerve defect amounted to 12 cm. There were cases of defects of the median, radial and ulnar nerves. Repeated chronaxia examinations were made; motor and sensory functions of the involved extremities were tested with electrometric instruments. Observations demonstrated that the implanted nerve acted as a dead tissue bridge, thereby assuring the regeneration of the nerve fibers. Usually, when motor and sensory functions are lost, a disturbance takes place in the circulation and perspiration of the extremity. It becomes cyanotic, clammy and often covered with ulcers. Every case of transplantation of the formaldehyde

treated nerve tissue showed an improvement in each of these dystrophic processes. The transplantation of human nerves in large peripheral nerve defects accelerates the regeneration and reestablishment of the lost motor, sensory and trophic functions and prevents the wounded from becoming invalids.

Vascular Diseases: Ninth Annual Review. T. R. Van Dellen, G. de Takáts and G. W. Scupham.—p. 518.

Immune Serum Therapy for Oroya Fever.—According to Howe there have been numerous attempts at immune therapy with serum or transfusions of whole blood from patients convalescing or recovered from various stages of Carrión's disease. The few available reports are inconclusive and neither substantiate nor detract from the possibility that such forms of passive immunization may be beneficial in certain cases. Arsenical preparations have been tried with unconvincing effects. The present communication deals with 3 cases of Oroya fever in which hyperimmune rabbit serum containing a high titer of agglutinins for *Bartonella bacilliformis* was given in moderately large intravenous doses. Immune serum was produced in rabbits by the intravenous administration of large amounts of *Bartonella bacilliformis* both in the fresh and in the formaldehyde treated state. There was no dramatic change in the clinical picture in any of the 3 cases as a result of immune serum therapy except for the prompt appearance of the typical eruption in 1 case. In this case the time of eruption was earlier than is usual in untreated Oroya fever. It is thought that intravenous administration of immune rabbit serum may have caused an appreciable diminution in the percentage of erythrocytes infected with *Bartonella bacilliformis*. A comparison is made of these cases with 5 cases of severe untreated Oroya fever from Colombia. The reduction of visible erythrocyte infection appears to be much more gradual in these cases than in those in which immune serum was used in treatment.

Acquired Hemolytic Anemia.—Mason shows that the anemia produced by accelerated disintegration of red blood cells leading to jaundice, increased excretion of urobilinogen and moderate splenomegaly is often accompanied by morphologic alterations of the red cells and is usually classified as hemolytic anemia. He observed a number of patients with hemolytic icterus of unknown cause and with acute or a subacute course similar to cases reported by Vidal and by Chauffard. He has records of patients with chronic acquired hemolytic anemia of unknown cause whose disease began acutely and followed a course characterized by a continuous increased hemolysis and by recurrent severe crises of hemolysis similar to those seen in acute acquired hemolytic anemia. The 12 cases reported here were observed subsequent to 1916. The disease is relatively rare. The cases of acute or chronic hemolytic anemia of the acquired type are characterized by more or less rapid destruction of erythrocytes. Splenomegaly is constant. It is probable that the destruction of blood occurs chiefly in the spleen. There is a pseudomacrocytic blood picture, usually with a high color index. Large numbers of macrocytes and microspherocytes are present in the blood film during the hemolytic crises in the acute type of the disease or constantly in the chronic type of the disease. The red cells may show extreme osmotic fragility or they may be normally resistant to hypotonic saline solutions. This abnormality is not related to the number of spherocytes in the circulating blood. The blood may or may not contain autoagglutinins or autohemolysins. The disease is neither hereditary nor congenital, and no etiologic factor has been determined in any of the reported cases. The acute type of

the disease has been reported as Lederer's anemia. Subacute and chronic types are probably more frequent than is commonly believed. The disease may heal spontaneously, or it may be cured by transfusions or by splenectomy. The more chronic types of the disease may or may not be cured by the removal of the spleen. During the serious hemolytic crisis removal of the spleen may be life saving even if it does not lead to complete cure.

Cold Hemagglutination with Symmetrical Gangrene of Tips of Extremities.—Stats and Bullowa point out that the antigen-antibody reaction between human erythrocytes and serum in which hemagglutination is observed only at low temperatures (below 68 F.) occurs in diverse pathologic states, such as Raynaud's syndrome, acute and chronic acquired hemolytic anemias, trypanosomiasis, acute bacterial infections, cirrhosis of the liver, leukemia, pernicious anemia, lymphoblastomas and bland venous thrombosis. Its presence in low titer has been recorded in at least 95 per cent of normal persons. There is only one previous report of the occurrence of gangrene of the extremities due to the action of a cold hemagglutinin. In the case reported by the authors an American Negro aged 64 noticed, fifteen years before admission, tingling, burning and numbness of the tips of his fingers and toes on exposure to a low environmental temperature. Two weeks prior to admission the patient was exposed to a temperature of approximately 5 F. for about sixty minutes while waiting for a bus. During this time he was clad warmly. He spent most of the hour standing still. He observed the same tingling of his fingers and toes that he had experienced many times before, and the first urine passed was dark. On his admission to the hospital the tips of the fingers to the distal interphalangeal joints were tense, tender, painful and cool to touch. In the lower extremities all the arterial pulses were easily felt. Both feet were moderately edematous and tender. The patient could not move his toes, and they were insensitive to pain stimuli. The toes were exquisitely tender and cool to touch. Laboratory studies revealed (a) unilateral hemoglobinemia following exposure of a forearm to cold, (b) hemagglutination in the capillaries of the conjunctiva due to cold and (c) absence of syphilis or evidence of a hemolytic anemia. No cause could be found to explain the presence of the cold hemagglutinin. A discussion is presented of clinical conditions in which transient or permanent arterial insufficiency of the extremities occurs despite adequate pulsation and absence of disease of the peripheral arteries. All the cases of cold hemagglutination reported in the literature in association with arterial insufficiency of the extremities or hemoglobinuria are tabulated.

*Fecal Impaction: Report of Unusual Case. A. M. May and E. Torre.—p. 224.

Fecal Impaction.—May and Torre report an unusual case of fecal retention. A woman aged 52 had shown progressive enlargement of the abdomen over a period of two years. She was emaciated, but her abdomen was enlarged to the size of a full term pregnancy. She claimed to have had no bowel movement for a year and a half. Her statement could not be believed, and a large ovarian cyst was thought of. Operation revealed that the descending colon from the splenic flexure to the sigmoid had become enormously dilated with feces, the bowel wall thinned to a cystlike appearance. An incision was made into the distended bowel and approximately 5 gallons of inspissated fecal material was removed. Search was made for an obstructive growth but none could be found. A temporary loop colostomy

tomy above the distended bowel was established. The patient's recovery was uneventful. Because of the recovery and the ultimate restoration of normal bowel activity, the authors feel that this case was a true fecal impaction rather than a megacolon of the Hirschsprung type.

Carbon Dioxide for Counteracting Effects of Low Oxygen.—A study of arterial and internal jugular blood and of brain function in 8 healthy young men who breathed mixtures containing low percentages of oxygen and varying rations of nitrogen and carbon dioxide revealed, according to Gibbs and his associates, that normal brain function can be maintained in spite of a low percentage of oxygen in the inspired air (as low as 2 per cent), provided the carbon dioxide tension of the body is maintained. The addition of carbon dioxide to low oxygen mixtures permits maximal utilization of the available oxygen because of (a) increased pulmonary ventilation and consequent increased oxygenation of the arterial blood, (b) peripheral vasoconstriction and cerebral vasodilatation, insuring to the brain a maximal share of the circulating blood, and (c) shift in the hemoglobin dissociation curve so that the blood unloads a greater proportion of its oxygen in the tissue. The improvement in the oxygen supply to the brain is only one aspect of the matter. The maintenance of the carbon dioxide tension of the brain is of equal importance for normal brain function. Gross cortical dysfunction manifested by high voltage slow activity in the electroencephalogram and by mental confusion

occurs when the carbon dioxide tension of the brain falls as a result of breathing low oxygen mixtures, even though the oxygen tension of the brain may be sufficient to maintain normal brain function. If the oxygen tension of the brain is lowered while the carbon dioxide tension of the brain is maintained, consciousness is lost without a preceding period of confusion and without the occurrence of high voltage slow waves in the electroencephalogram.

Brewers' Yeast as Supplement to Industrial Lunch.

Heller and her collaborators sampled the noon meal served to workers in a cafeteria in the Brooklyn Navy Yard for the riboflavin, niacin and thiamine contents. It was found that this noon meal usually furnishes at most only one fourth of the day's requirements for these vitamins. Dry brewers' yeast has provided a satisfactory method of supplementing the supply of these vitamins. This yeast was usually incorporated in the meat dishes at conservative levels, so that the taste was not detected. Since yeast is rich in protein of good quality it also affords a good source of this dietary factor.

Wilms Tumor of Kidney.—Weisel and his associates studied records of 101 patients who were seen at the Mayo Clinic from 1904 to 1940 inclusive and whose condition was diagnosed as Wilms tumor, embryonal sarcoma, mixed tumor of the kidney or sarcoma of kidney. A careful weeding out revealed 44 Wilms tumors. Wilms tumor (embryonal carcinosarcoma of the kidney) is a malignant mixed tumor of the kidney seen primarily in childhood, but it can occur at any age. The most prominent clinical feature is an abdominal mass. Fever, emaciation and hematuria are common. The clinical course is progressive and as a rule rapidly downhill. The treatment of choice is prompt surgical extirpation combined in certain cases with preoperative irradiation and always followed by postoperative roentgen treatment. The majority of patients fail to survive one year. In the present series only 7 of the 44 patients were living two to twenty years after operation. The pathologic diagnosis of Wilms tumor depends on the find-

ing of glandular and stromal cells in a more or less characteristic mixed tumor arrangement. Other types of tissues, notably striated muscle, are found in about half of the cases. The origin of Wilms tumors is obscure.

- Three New Tools of Science. D. F. Winnek.—p. 1986.

Renal Lesions in Hypertension.—Aschner and his associates describe their urographic studies on 100 patients with hypertension and present illustrative case reports on renal lesions in hypertensive patients. They feel that in view of the newer knowledge of arterial hypertensive disease internists should insist on a urologic study of all such patients, excretion urography being the minimal requirement. Urologists should give more attention to the blood pressure trends in their patients in order to detect incipient hypertension and evaluate its relationship to the urologic disorder. Pathologists should study the main renal vessels in kidneys removed at operation and obtained post mortem. Discovery of obstructive uropathies in their early stages is the duty of every practitioner. The exhibition of the newer urinary antiseptics (mandelates, sulfonamides) may materially lessen the incidence of progressive pyelonephritis. The relationship of a unilateral renal lesion to coexistent hypertension is an individual problem. In occasional instances it is a definite etiologic factor, in some instances it is contributory, in most it is coincidental. The decision regarding nephrectomy in hypertensive patients should be based on the nature of the renal lesion alone, with due reference to consideration of conservation of renal tissue which may later stand the patient in

good stead. When the causal relationship of a unilateral renal lesion to hypertension seems probable, early recognition of this relationship, with prompt nephrectomy, enhances the likelihood of a good result.

Vitamin B₆ (Pyridoxine Hydrochloride) in Radiation Sickness.—Maxfield and his associates call attention to the great variation in the reaction to radiation therapy. Its severity is apparently dependent on some inherent susceptibility in the patient. A patient suffering from malnutrition, debilitation and avitaminosis will usually not tolerate radiation therapy as well as a patient in good nutritional balance. There are many patients in whom vitamin B₁ and vitamin B complex are not effective. The authors administered 25 mg. of pyridoxine hydrochloride intravenously to patients in whom a definite radiation sickness was present. In most instances only one injection was necessary to stop the unfavorable symptoms. The authors recommend that 25 mg. be given intravenously immediately after the onset of radiation sickness and repeated at intervals of twenty-four to seventy-two hours as needed. The results have been most gratifying in a series of over 50 cases. Vitamin B₆ should supplement and not replace other methods. The use of liver extract, a high vitamin intake and sedatives is to be encouraged.

Effects of Plasmochin, Atabrine and Quinine on Electrocardiogram.—Heimann and Shapiro observed that leads 4 R and 4 F showed changes of the coronary type in a soldier aged 22 who complained of precordial pain while receiving plasmochin. Observations on convalescent malaria patients showed that plasmochin increased the amplitude of the various deflections, affecting the T wave most constantly. In some cases the most striking feature was the effect on the S-T segment which simulates the cardiogram of coronary thrombosis. Atabrine decreased the amplitude of the various deflections, also affecting the T wave most noticeably and constantly. It restored the S-T segment to the isoelectric level after it had been elevated by plasmochin. Quinine had an effect similar to atabrine but to a lesser degree. Differentiation between the effects of plasmochin on the one hand, and of atabrine and quinine on the other, in a particular patient may be made on the electrocardiographic findings. Plasmochin increased the size of the T wave above normal while quinine and atabrine decreased it below normal. Plasmochin often has an effect on the S-T segment, as described; this is not seen in the exhibition of either of the other two drugs.

Herpes Zoster Ophthalmicus.—Parry and Laszlo direct attention to the occurrence of various ophthalmic conditions caused by herpes zoster. A woman aged 52 had an attack of herpes zoster along the ophthalmic branch of the right fifth nerve six weeks previously. The cornea was not involved, but there was a skin eruption with severe pain. Three and a half weeks after the eruption she suddenly lost sight in her right eye. The disorder was diagnosed as acute retrobulbar neuritis. After five weeks the visual acuity of the patient had improved. A man aged 33 had had "shingles" on his chest. Three weeks later he felt giddy and had double vision. Examination revealed paresis of the right abducent nerve. The condition gradually cleared up. The few existing statistics on the late ophthalmic involvements in herpes zoster reveal that they occur in the

following order of frequency: iridocyclitis (usually a complication with keratitis), optic neuritis and paralysis of the third, fourth and sixth cranial nerves. Retrobulbar neuritis has not been previously mentioned as a signal of herpes zoster.

James Barry—1792 (?)—1865 Inspector General of Army Hospitals. M. P. Russell.—p. 558.

Internal Pneumonolysis.—Barclay reports 103 thoracoscopies which were performed on 80 patients. There were two types of cases. One group included 57 patients in whom the cavity was held out by adhesions. Another group included 23 patients in whom adhesions prevented a concentric collapse of the lung which still contained active disease. In the first group the adhesions had to be divided because the pneumothorax was ineffective; in the second group continued traction exerted by the adhesions resulted in premature reexpansion of the lung. The method used was double puncture under local anesthesia. The author used the cautery alone and never encountered troublesome bleeding. In 50 of the patients complete division was effected and the disease was controlled; in 8 patients division was incomplete but the disease was nevertheless controlled; in 12 patients the disease remained uncontrolled because of incomplete division; in the remaining 10 patients it was not possible to cut the adhesions because of fusion of the lung with the chest wall. There were no deaths, and the patients were little upset by the intervention. Apart from 1 patient who developed a purulent effusion, the only complication encountered was a serous effusion, which occurred in 10 per cent of the patients. Section of adhesions converted over 70 per cent of unsatisfactory type of pneumothorax into a satisfactory type.

Urinary Tract Infections in Royal Navy. J. Shafar.—p. 446.

Pneumonitis Associated with Autohemagglutination.—Shone and Passmore report observations on 54 consecutive cases of pneumonitis which occurred among Indian troops shortly after their arrival in the Middle East. The cases are divided into four groups: (1) atypical pneumonia, (2) short fever with cough and persistent lung signs, (3) afebrile laryngitis with little or no lung involvement and (4) proved malaria or splenomegaly with laryngeal or lung involvement. While investigating 1 of these cases of fever the authors observed that when a drop of blood was placed on a slide the red corpuscles immediately separated into clumps. An investigation in the medical wards led to the recognition of the described group of cases in which the predominant clinical features were fever and cough, the latter often associated with vomiting, hoarseness of voice and the presence of fine crepitations in the lungs: all showed the phenomenon of agglutination of red corpuscles. The men had been in camp near Delhi, where the incidence of fresh malarial attacks was high and some of them were still suffering from the effects of this disease. The authors sought for autohemagglutination in 331 Indian troops other than those with pneumonitis. The incidence was particularly high in patients with malaria. Many rickettsial infections involve the lungs, setting up a pneumonitis or interstitial pneumonia, and it is therefore relevant that all the patients examined were heavily infested with lice. The association of chronic malaria with so

many of the cases must suggest the possibility of a malarial basis for the disease, but an outbreak of malarial pneumonitis is outside all previous experience.

*Concentration and Drying of Serum for Intravenous Use. Marjorie Bick.—p. 227.

Concentration and Drying of Serum for Intravenous Use.—Bick describes a method of drying serum by precipitation of the serum proteins with alcohol and ether after preliminary concentration in cellophane casings. This process, which is known as hardyization, gives a finely divided product which can be dissolved readily, giving a perfectly clear reconstituted serum. The method so far has been used for drying 600 cubic centimeter lots of serum. No difference was observed between the serum protein concentration, the serum titer or group specific reducing power of the wet serum and that of dried serum reconstituted to its original volume. The advantages of this method of drying serum are the appearance of the product, the ease with which the dried serum can be reconstituted and the clearness of the reconstituted fluid. This clearness is due partly to the absence of fat and other lipoid material but also to the absence of denaturation of the protein. If the solvent is not properly cooled and the serum is not added slowly, a product which is hard to dissolve and gives a turbid reconstituted fluid may be obtained. The disadvantages of this method are the cost of the large volumes of ether used and the difficulty of transferring aseptically the dried product from the funnel to the bottle in which it is stored and reconstituted before administration. Since January 1941 90 pints of serum has been dried by this method, of which 80 has been reconstituted and given to patients. No unfavorable reactions were recorded. The reconstituted serum was invariably found to be sterile. Economy of solvent is effected by the preliminary concentration of the serum to one third of its original volume in cellophane casings. There appears to be no great difficulty in recovering the ether if the process is carried out on a large scale.

*Treatment of Habitual Shoulder Dislocation by Means of Metal Barrier Secured on Neck of Scapula and Coracoid Process. R. Ramser.—p. 377.

Mobile Duodenum.—Geigy observed in 1940 and 1941 5 patients with mobile duodenum who required surgical treatment because of severe and recurrent complaints. Mobile duodenum must be differentiated from ptosis of the duodenum which is caused by looseness of the retroperitoneal tissue. It is the result of a congenital malformation. It may be caused by failure (1) of the anterior loop to rotate around the vertical axis, (2) of the pyloric antrum and of the pars superior duodeni to rotate clockwise around its sagittal axis or (3) of the umbilical loop to rotate counterclockwise around the sagittal axis. The result is absence of duodenojejunal flexure. The

condition may also be caused by a lack of fixation of the duodenum to the posterior abdominal wall. Total mobile duodenum is comparatively rare. The majority of cases of mobile duodenum involve the superior part. As long as duodenal passage and bile discharge are not impaired, mobile duodenum is merely an anatomic defect which may be accidentally discovered by the roentgenologist. If symptoms develop, a mild dyspepsia, cholecystitis or duodenal ulcer may be simulated. The patients complain of a feeling of pressure in the epigastric region. The disturbance is not dependent on foods, so that dietetic treatment is ineffective. Nausea is frequent but vomiting is rare. If the duodenum is mobile beyond the duodenal papilla, biliary symptoms may predominate. There may be pain along the right costal arch with radiation toward the back and shoulder. The patients are usually of the asthenic type. General or partial ptosis may exist simultaneously. The clinical aspects generally do not suffice for a definite diagnosis and roentgenoscopy in different postures must be resorted to, although even this may lead to a mistaken diagnosis of ulcer or adhesion. Patients with mild symptoms require only medical treatment, but those with severe, relapsing disorders require surgical correction. Fixation to the posterior abdominal wall is one type of operation. Duval recommends posterior duodenopexy with simultaneous antropyloroduodenal attachment by means of a distally mobilized ligamentum teres hepatis. Duodenojejunostomy or gastroenterostomy may counteract stasis but will not correct the malformation. Since none of these methods have given complete satisfaction, Henschen suggested antroduodenal resection with retrocolic, posterior gastroenterostomy. The author employed this operation in the 5 cases.

Treatment of Habitual Shoulder Dislocation with Metal Barrier.—Ramser corrected habitual dislocation of the shoulder in a girl aged 18 by means of Brun's modification of Eden's method. A correctly measured piece of bone from the tibia had been inserted into a pocket on the anterior surface of the neck of the scapula, and immobilization of the arm had been maintained for seven weeks. Two years later the head of the humerus luxated forward repeatedly. A second operation revealed that the transplanted bone was completely absorbed. The author decided to employ nonabsorbable material. He used a clasp of rust free steel. The long peg, measuring 5 cm., was driven in extracapsularly at the edge of the glenoid cavity. It extended 1.5 cm. outward beyond the cavity; the shorter peg, measuring only 2.5 cm., was driven completely into the coracoid process. The middle piece, to which the two pegs stand vertically, measured 4 cm. and was slightly curved. The arm was immobilized for several days in an abduction splint and then gymnastic exercises were begun. Three weeks later the patient was able to assist in hay making. Suturing of the capsule to the short biceps tendon prevents slipping out of the metal clasp. Its deeper penetration is prevented by the coracoid process. In another patient a metal barrier was added to a bone implantation.

*Direct Transmission of Rickettsia Prowazeki to Lungs of Mice from Human Sternal Marrow. E. Benhamou, R. Horrenberger and G. Renoux.—p. 53.

Antimalarial Campaign in Department of Algiers in 1942. E. Collignon.—p. 55.

Report of Functions of Pasteur Institute of Algeria. E. Sergeant.—p. 89.

Transmission of Rickettsia Prowazeki to Lung of Mice from Human Sternal Marrow.—Benhamou and his collaborators state that the direct transmission of Rickettsia prowazeki from human sternal marrow to the lung of mice had its point of departure from the observation of one of the authors that Rickettsia prowazeki is encountered regularly in the sternal marrow of patients with exanthematic typhus in quantities sufficient to detect them by direct microscopic examination of slide specimens. From this time sternal marrow was used for the experimental transmission to receptive animals, particularly to those which serve for the production of typhus vaccine. The material which was used for inoculation was

obtained from patients with exanthematic typhus in whom the more or less characteristic picture was always confirmed by direct demonstration of Rickettsia prowazeki in the bone marrow slides. The sample obtained by sternal puncture was diluted in a small quantity of isotonic solution of sodium chloride and inoculated into 4 mice by the respiratory route and into 2 rabbits by the intracerebral and peritoneal routes. Subsequent passages from mouse to mouse were made by respiratory inoculation of ground pulmonary tissue and from rabbit to rabbit by intraperitoneal inoculation of ground brain tissue. In one out of five attempts it has been possible to isolate a strain of Rickettsia prowazeki and to adapt it to the lung of mice without passing it through an intermediate host such as rabbit or louse. This proves the high infective power of the bone marrow.

*Malignant Lymphogranulomatosis with Compression of Lymph Nodes Causing Serofibrinous Pleurisy and Jaundice in Children. H. J. Notti, H. V. Ferrer and A. Grinfeld.—p. 403.

Bone Changes in Leukemia in Children. J. A. Soto.—p. 415.

Malignant Lymphogranulomatosis in Children.—Notti and his associates report 4 typical cases of malignant lymphogranulomatosis in children between the ages of 3 and 8 years. Sternberg's cells were encountered in the blood of all 4 patients. Two of the patients presented, in addition to the enlargement of the cervical, axillary and mediastinal lymph nodes, enormously enlarged liver and spleen and anemia. Kahn, Pirquet and tuberculin tests were negative and the sputum did not contain tubercle bacilli. One of the patients developed a serofibrinous pleurisy as a result of compression by the mediastinal lymph nodes. Diffuse edema, dyspnea, cough and prostration were the predominant symptoms in the final stage of the disease. The other patient developed acute jaundice. Exploratory laparotomy in this case revealed compression of the hepatic and common bile ducts by enlarged lymph nodes. Roentgen, radium, arsenic and liver therapy failed to arrest the progress of the disease, in these cases which terminated fatally in about two years.

*Value of Lymph Node Puncture as Diagnostic Procedure. M. Pio da Silva.—p. 69.

Lymph Node Puncture.—Pio da Silva studied 29 cases of lymph node enlargement of various pathologic types. In all cases examination of the dry smear of material obtained by puncture was compared with the microscopic examination of the lymph node. May-Grünwald-Giemsa's method of staining was used in all smears. The lymph node puncture permitted the diagnosis of tuberculosis in 7 out of 12 cases either through the finding of tubercle bacilli or because of the presence of typical epithelioid and giant cells. In each of the 8 cases of blastomycosis smears revealed the presence of Blastomyces. In 4 cases of metastatic carcinoma the presence of numerous neoplastic cells in the punctate permitted a correct diagnosis to be made. In 2 cases of Hodgkin's disease the punctate revealed Reed-Sternberg cells and numerous eosinophils characteristic of the disease.

*Simple Atrophy of Optic Disk: A Sign of Subtentorial Tumor. M. Puig Solanes.—p. 199.

Atrophy of Optic Disk in Subtentorial Tumor.—Puig Solanes directs attention to the diagnostic value of simple atrophy of the optic disk in tumors of the fourth ventricle or of the cerebellum. Optic atrophy in these cases is the result of the acute dilatation of the ventricular system. Because ventriculography is contraindicated in certain cases of cerebral tumors, the diagnostic value of simple atrophy of the optic disk is obvious. Simple atrophy of the optic disk in patients with symptoms of intracranial hypertension and other signs of

involvement of cerebral structures in the posterior cranial fossa is pathognomonic of a tumor in these localizations. The diagnostic value of simple atrophy of the optic disk in the foregoing conditions is so reliable that it renders ventriculography unnecessary. The author reports 4 cases in which the diagnosis was verified by removal of the tumor from either the fourth ventricle or the cerebellum.

*Latent Liver Cirrhosis. R. Solé.—p. 1525.

Total Skin Free Graft. E. F. Malbec.—p. 1576.

Latent Liver Cirrhosis.—According to Solé, cirrhosis of the liver is a slowly developing process which in its early stage may produce no clinical symptoms or only atypical syndromes. Clinical and pathologic observations on the latent stage of liver cirrhosis are reported in 12 cases in which exploratory intervention was done because of gastrointestinal hemorrhages of undetermined etiology or because of a diagnosis of biliary stones or abdominal tumors. The only pathologic alteration found at the operation was a more or less severe cirrhosis of the liver diagnosed by biopsy. In all instances the exploratory laparotomy and the later course of the disease ruled out malignant neoplasm and biliary or gastric lesions. Histopathologically the liver proved to be the site of degenerative or inflammatory processes accompanied by connective tissue proliferation around and/or inside the hepatic lobules. Cirrhosis was associated with fatty degeneration of the hepatic cells, more or less extensive foci of necrosis, round cell infiltration, proliferation of vascular endothelium and Kupffer's cells, irregular regeneration of hepatic cells and of biliary canaliculi. Liver damage was always sufficiently extensive to account for a number of clinical syndromes including gastrointestinal hemorrhages; colicky pain with or without jaundice, usually diagnosed as biliary duct stones; anemia, loss of weight, anorexia and asthenia, sometimes with a rather rapid course resembling malignant tumor; and various types of dyspepsia. Cirrhosis of the liver should always be considered in similar instances when the etiologic factors are unknown.

*Sulfathiazole in Treatment of Dysentery and Acute Diarrhea in Children: Observations on 236 Cases. M. Altenfelder, P. P. Corrêa, Maria P. Moreira de Moraes, Alaide Mello Sá and L. Camargo Pentendo.—p. 15.

Sulfathiazole for Dysentery and Acute Diarrhea in Children.—Altenfelder and his associates employed sulfathiazole in the treatment of 236 children under 30 months of age with acute diarrhea, bacillary dysentery and amebic dysentery. The drug was administered in doses of 2 grains (0.13 Gm.) every six hours for a period of four days, regardless of the weight or the age of the patient. The drug was effective in all cases in which examination of the stool revealed *Escherichia coli*, *Salmonella*, *Shigella dysenteriae* and *Shigella paradysenteriae*. Complete recovery occurred within four days in this group. The drug had no beneficial effect on dysentery caused by *Lamblia intestinalis* and *Amoeba dysenteriae*. The tolerance to sulfathiazole was remarkable by all children except 1, who vomited and was unable to take the drug. No toxic symptoms were observed.

*Acute Confusional State Associated with Waterhouse-Friderichsen's Syndrome. H. Hoff and J. A. Shaby.—p. 245.

Subacute Leukoencephalitis. T. Fracassi.—p. 261.

Acute Confusion Associated with Waterhouse-Friderichsen's Syndrome.—Hoff and Shaby report clinical and pathologic observations on 16 patients presenting acute mental confusion associated with features of acute severe infectious

disease with high temperature, shock, dehydration and loss of weight. In all cases there was a definite psychic disturbance and change of personality immediately preceding the onset of acute symptoms. The course of the disease was followed in 11 cases. The first 8 cases observed ended fatally in from five to twenty-one days. Postmortem examination revealed slight edema and congestion of the brain, distention of the thyroid follicles and extensive hemorrhages of the adrenal cortex. The clinical and pathologic features were considered by Hoff and Shaby as identical with those observed in the Waterhouse-Friderichsen syndrome associated with a condition of acute mental confusion. Accordingly, treatment with adrenal cortex extract, vitamin C and intravenous injections of metrazol was instituted in the last 4 cases observed. Recovery occurred in 3 of these 4 cases.

*Genital Tuberculosis: Relation to Sterility. E. Twaites Lastra and A. Jakob.—p. 536.

Bilateral Tuberculosis of Breast. A. Egües and R. I. Latienda.—p. 554.

Genital Tuberculosis.—Thwaites Lastra and Jakob found tuberculosis of the endometrium in 14 of 1,098 women in whom curettage was performed. Tuberculosis of both fallopian tubes and of the endometrium was encountered in 12 of 840 women operated on for gynecologic disease. Tuberculosis of the internal genitalia lacks pathognomonic clinical signs. Seventy per cent of the patients complained of hemorrhages and of pain in the iliac fossae which increased during menstruation. None of the patients had clinical symptoms or x-ray signs of pulmonary tuberculosis. The authors believe that primary endometrial tuberculosis is more frequent than was formerly believed; it is the cause of sterility in about 7 per cent of the cases. Tubercle bacilli travel by way of the local lymphatic system from the intestine to the parametrium and parametrial and endometrial lymph nodes.

*Cirrhosis of the Liver and Medical Progress. A. Prat Echaurren and R. Jorquera.—p. 755.

Cirrhosis of the Liver.—Echaurren and Jorquera analyzed the data on 36 cases of cirrhosis of the liver followed for a period of one and a half years. According to the presence or absence of clinical signs of liver insufficiency, such as jaundice, hemorrhages, or ascites, the cases were classified in two groups: active and latent cirrhosis. In 80 per cent of 29 cases which were in an active, progressive stage, death occurred within twelve months of the onset of clinical symptoms. The presence or absence of hypertrophy or atrophy of the organ had no relation to the rate of progressiveness of the disease. The majority of the patients with active cirrhosis of the liver presented jaundice, high sedimentation rate, low prothrombin levels, low plasma protein levels, chloride retention especially in the globules, low chloride urinary excretion, oliguria, positive Takata-Ara reaction and low cholesteremia. Oliguria below 500 cc. daily and chloride urinary excretion lower than 2 Gm. per day were regularly associated with a very poor prognosis. In the group with latent liver cirrhosis the sedimentation rate was high as a rule, prothrombin levels were low in 60 per cent, and the Takata-Ara reaction was positive in all cases. Clinical symptoms in this group were scarce and atypical. Latent cirrhosis of the liver should always be considered in patients having pain in the hepatic region, biliary colic, gastrointestinal hemorrhages of undetermined origin, diarrhea, asthenia and history of alcohol addiction. All methods of treatment failed to prevent the progressive course of the active cirrhosis. In 7 out of 10 cases the daily administration of 600 mg. of inositol, combined with a high protein diet, was associated with gain in weight, disappearance of gastrointestinal

symptoms, increase in diuresis and a definite subjective improvement. Echaurren and Jorquera point out that this method of treatment deserves further investigation, particularly in the early stages of cirrhosis of the liver.

*Monocytic Angina, Also Called Infectious Mononucleosis. J. Matusevich.—p. 599.

Asthma and Insufficiency of Liver. G. A. Barros.—p. 610.

Monocytic Angina.—This is a frequent infection. The disease appears in epidemic outbreaks. It is more frequent in children and young persons. The diagnosis is made from clinical symptoms from repeated examinations of the blood and from the serologic test. The clinical symptoms are those of any general infection with or without acute tonsillitis, cervical and submaxillary adenitis and fever. Acute tonsillitis is present in the majority of the cases. It is generally unilateral. Local fusospirillar symbiosis is almost constant, but Löffler's bacteria are not found. There may be enlargement of the lymph nodes of the axilla and of the groin and splenomegaly. Adenitis and the acute fever which appear early in the course of the disease may disappear rapidly or persist for weeks or months. Fever declines by lysis and frequently recurs for several short periods. The erythrocytes are normal. The study of white cells is indispensable for a diagnosis. There is a leukocytosis between 10,000 and 40,000 and a high mononucleosis with predominance of monocytes and lymphocytes. A positive Davidsohn serologic test is specific for the disease. Administration of calcium and liver preparations and of vitamins shortens the course of the disease and renders the symptoms milder.

*Atypical Forms of Poliomyelitis. E. Strangmann.—p. 38.

Acute Atrophy of Liver During Childhood. E. Gasser.—p. 49.

Atypical Forms of Poliomyelitis.—Strangmann shows that in addition to the classic spinal form of poliomyelitis there exist nonparalytic, meningitic, cerebral and cerebellar types. He describes atypical cases of poliomyelitis observed by him during the summer and fall of 1941. The nonparalytic meningitic forms were particularly numerous. There were also cerebral forms and encephalitis-like disturbances with rapidly changing mental symptoms. These types are of particular significance for the early diagnosis of poliomyelitis. During epidemics it is essential to pay attention to all the known prodromal symptoms and to perform spinal punctures whenever meningitic symptoms are present. While nonparalytic cases of poliomyelitis furnish valuable convalescent serum, the fact that some of these cases are incorrectly diagnosed reduces the value of such serum.

Whole Grain Flour in Formula of Babies and in Diet of Infants. H. Gronau.—p. 660.

Objections Against Diet Opposed to Carcinoma. M. Weiser.—p. 663.

Carcinoma of Stomach and Gastritis.—Westhues considers three types of clinical courses of gastric carcinoma. The first type is represented by cases with a long, severe course caused by a chronic, severe gastritis. Chronic gastritis is different from atrophic gastritis. Carcinoma may have developed from gastritis in some of the cases, but causal relationship between carcinoma and severe chronic gastritis may be absent in other cases, while the gastritis may be secondary, caused by primary blastomatous polypi in still other cases. This group

is small. A long history usually divided into two phases will be found in the second group. The first phase may sometimes be traced for many years. This, so-called "preanamnesis," is characterized by mild clinical disturbances ("weak stomach"). Thus a mild type of chronic gastritis may be the pathologic-anatomic basis from which, however, carcinoma will not develop, or there may be gastritis of old age or even a gastrosis, which does not depend on inflammation. It may be a predisposing "specific" condition of mucous membrane from which carcinoma may result. In the first instance the preanamnesis is not related to the later occurrence of carcinoma; in the second type one deals with a true preanamnesis of carcinoma as related to gastritis of old age or to gastrosis. The preceding history therefore is not of practical importance when one considers the frequency of mild common gastritis. The second and short phase refers to the true severe carcinoma—gastritis associated with a more or less acute onset during the last few months. It is an acute gastritis caused by a carcinoma developing on a basis of an existent chronic gastritis-gastrosis. The true carcinoma-gastritis thus always presents a chronic atrophic gastritis associated with an acute onset. This gastritis is associated with acute exacerbation and cannot be the cause of the carcinoma. The long mild anamnesis with two phases does not support the concept that inflammation is of essential importance in the genesis of carcinoma. The classic short anamnesis is found in the third group. From the pathologic-anatomic point of view one deals with the same chronic atrophic gastritis on which the principal history of the previous group has been based, but clinical symptoms have not resulted from the gastritis of old age. The severe gastritis to which the short anamnesis refers is secondary and is thus not responsible for the carcinoma. The time factor in these cases is also opposed to the inflammatory genesis of carcinoma. Gastritis may play, however, a certain incentive role although carcinoma is not of inflammatory origin in the majority of the cases. The treatment of gastritis (particularly resection for gastritis) may play some part in the prophylaxis of carcinoma. But incidence of carcinoma will not be decisively reduced by this type of treatment. Early treatment of carcinoma based on early diagnosis is the main prophylaxis of carcinoma. The long history calls for a particularly careful clinical examination and continued control of the individual case.

Roentgenologic Examinations of Kidneys. L. Stelir.—p. 534.

Bactericidal Action of Synthobilin, a Choleretic Substance. B. Kemkes.—p. 540.

Lambliasis Intestinalis.—At Rissmann's hospital in Krakow it was the rule to perform duodenal aspiration on all patients with gastrointestinal disturbances and it was found that lambliasis was about as frequent as bacillary dysentery. Twenty-six cases of lambliasis were observed during the same period in which 25 cases of bacillary dysentery occurred. The largest number of cases occurred when lettuce and radishes appeared on the market in larger quantities, that is during the months from June to October. Rissmann rejects the idea that *Lambia intestinalis* is a harmless parasite. An alkaline milieu greatly favors its development. The lamblias flourishes in the duodenum particularly when gastric aspiration reveals anacid or subacid values. Eight of the author's patients had no free hydrochloric acid, 12 had subacid values, 5 had normal acidity and only 1 had hyperacidity. There are 3 types of lambliasis: the gastrointestinal, the cholangitic-hepatic and the cachectic form. One type develops chronologically from another if the disease is not detected and treated during the early stages. Acridine dye derivatives such as atabrine and acranil are most effective in the treatment. The therapeutic success should be controlled by duodenal aspiration. All hygienic measures against intestinal infections are directed also against lambliasis. Duodenal aspiration should be done in every persistent epigas-

involvement of cerebral structures in the posterior cranial fossa is pathognomonic of a tumor in these localizations. The diagnostic value of simple atrophy of the optic disk in the foregoing conditions is so reliable that it renders ventriculography unnecessary. Latent Liver Cirrhosis.—According to Solé, cirrhosis of the liver is a slowly developing process which in its early stage may produce no clinical symptoms or only atypical syndromes. Clinical and pathologic observations on the latent stage of liver cirrhosis are reported in 12 cases in which exploratory intervention was done because of gastrointestinal hemorrhages of undetermined etiology or because of a diagnosis of biliary stones or abdominal tumors. The only pathologic alteration found at the operation was a more or less severe cirrhosis of the liver diagnosed by biopsy. In all instances the exploratory laparotomy and the later course of the disease ruled out malignant neoplasm and biliary or gastric lesions. Histopathologically the liver proved to be the site of degenerative or inflammatory processes accompanied by connective tissue proliferation around and/or inside the hepatic lobules. Cirrhosis was associated with fatty degeneration of the hepatic cells, more or less extensive foci of necrosis, round cell infiltration, proliferation of vascular endothelium and Kupffer's cells, irregular regeneration of hepatic cells and of biliary canaliculi. Liver damage was always sufficiently extensive to account for a number of clinical syndromes including gastrointestinal hemorrhages; colicky pain with or without jaundice, usually diagnosed as biliary duct stones; anemia, loss of weight, anorexia and asthenia, sometimes with a rather rapid course resembling malignant tumor; and various types of dyspepsia. Cirrhosis of the liver should always be considered in similar instances when the etiologic factors are unknown.

Main Indications of Roentgenotherapy in Dermatology. J. P. Vieira.—p. 3.

*Sulfathiazole in Treatment of Dysentery and Acute Diarrhea in Children: Observations on 236 Cases. M. Altenfelder, P. P. Corrêa, Maria P. Moreira de Moraes, Alaide Mello Sá and L. Camargo Penteado.—p. 15.

Sulfathiazole for Dysentery and Acute Diarrhea in Children.—Altenfelder and his associates employed sulfathiazole in the treatment of 236 children under 30 months of age with acute diarrhea, bacillary dysentery and amebic dysentery. The drug was administered in doses of 2 grains (0.13 Gm.) every six hours for a period of four days, regardless of the weight or the age of the patient. The drug was effective in all cases in which examination of the stool revealed *Escherichia coli*, *Salmonella*, *Shigella dysenteriae* and *Shigella paradysenteriae*. Complete recovery occurred within four days in this group. The drug had no beneficial effect on dysentery caused by *Lamblia intestinalis* and *Amoeba dysenteriae*. The tolerance to sulfathiazole was remarkable by all children except 1, who vomited and was unable to take the drug. No toxic symptoms were observed.

*Acute Confusional State Associated with Waterhouse-Friderichsen's Syndrome. H. Hoff and J. A. Shaby.—p. 245.

Subacute Leukoencephalitis. T. Fracassi.—p. 261.

Acute Confusion Associated with Waterhouse-Friderichsen's Syndrome.—Hoff and Shaby report clinical and pathologic observations on 16 patients presenting acute mental confusion associated with features of acute severe infectious

disease with high temperature, shock, dehydration and loss of weight. In all cases there was a definite psychic disturbance and change of personality immediately preceding the onset of acute symptoms. The course of the disease was followed in 11 cases. The first 8 cases observed ended fatally in from five to twenty-one days. Postmortem examination revealed slight edema and congestion of the brain, distention of the thyroid follicles and extensive hemorrhages of the adrenal cortex. The clinical and pathologic features were considered by Hoff and Shaby as identical with those observed in the Waterhouse-Friderichsen syndrome associated with a condition of acute mental confusion. Accordingly, treatment with adrenal cortex extract, vitamin C and intravenous injections of metrazol was instituted in the last 4 cases observed. Recovery occurred in 3 of these 4 cases.

Neurinoma of Anterior Cervical Region: Case. E. A. Votta.—p. 523.

*Genital Tuberculosis: Relation to Sterility. E. Twaites Lastra and A. Jakob.—p. 536.

Bilateral Tuberculosis of Breast. A. Egües and R. I. Latienda.—p. 554.

Genital Tuberculosis.—Thwaites Lastra and Jakob found tuberculosis of the endometrium in 14 of 1,098 women in whom curettage was performed. Tuberculosis of both fallopian tubes and of the endometrium was encountered in 12 of 840 women operated on for gynecologic disease. Tuberculosis of the internal genitalia lacks pathognomonic clinical signs. Seventy per cent of the patients complained of hemorrhages and of pain in the iliac fossae which increased during menstruation. None of the patients had clinical symptoms or x-ray signs of pulmonary tuberculosis. The authors believe that primary endometrial tuberculosis is more frequent than was formerly believed; it is the cause of sterility in about 7 per cent of the cases. Tubercle bacilli travel by way of the local lymphatic system from the intestine to the parametrium and parametrial and endometrial lymph nodes.

*Cirrhosis of the Liver and Medical Progress. A. Prat Echaurren and R. Jorquera.—p. 755.

Cirrhosis of the Liver.—Echaurren and Jorquera analyzed the data on 36 cases of cirrhosis of the liver followed for a period of one and a half years. According to the presence or absence of clinical signs of liver insufficiency, such as jaundice, hemorrhages, or ascites, the cases were classified in two groups: active and latent cirrhosis. In 80 per cent of 29 cases which were in an active, progressive stage, death occurred within twelve months of the onset of clinical symptoms. The presence or absence of hypertrophy or atrophy of the organ had no relation to the rate of progressiveness of the disease. The majority of the patients with active cirrhosis of the liver presented jaundice, high sedimentation rate, low prothrombin levels, low plasma protein levels, chloride retention especially in the globules, low chloride urinary excretion, oliguria, positive Takata-Ara reaction and low cholesteremia. Oliguria below 500 cc. daily and chloride urinary excretion lower than 2 Gm. per day were regularly associated with a very poor prognosis. In the group with latent liver cirrhosis the sedimentation rate was high as a rule, prothrombin levels were low in 60 per cent, and the Takata-Ara reaction was positive in all cases. Clinical symptoms in this group were scarce and atypical. Latent cirrhosis of the liver should always be considered in patients having pain in the hepatic region, biliary colic, gastrointestinal hemorrhages of undetermined origin, diarrhea, asthenia and history of alcohol addiction. All methods of treatment failed to prevent the progressive course of the active cirrhosis. In 7 out of 10 cases the daily administration of 600 mg. of inositol, combined with a high protein diet, was associated with gain in weight, disappearance of gastrointestinal

Book Notices

History of Surgery. By Richard A. Leonardo, M.D., Ch.M., F.I.C.S. Cloth. Price, \$7.50. Pp. 501, with 100 plates. New York: Froben Press, 1943

The appearance of the first history of surgery in English will be welcomed by members of the medical profession. The volume contains 370 pages of text, 56 pages of bibliography, 23 pages of index and 100 plates of illustrations grouped together as a sort of appendix to the text. To condense the subject matter at hand into 376 pages calls for skill in condensation, selection and balance rarely possessed by the casual writer. In appraising this difficult task the reviewer is quite conscious of the difficulties which confronted the author. The chapters dealing with the practices of the ancient peoples contain much that is interesting and instructive. The subsequent chapters show some of the disadvantages of trying to tell much in short space. There appear some avoidable errors, minor inaccuracies, errors in overemphasis as well as in understatement and errors of omission and of judgment. Most of these are not of great importance and do not impair the value of the work. Attention is called to them merely because the reviewer feels that the function of "a history" is to eliminate errors rather than to perpetuate them.

Military surgery is dealt with in three pages and does not contain the names of Larrey, Pirogov or von Bergmann. In the chapter on thoracic surgery the subject of pulmonary embolectomy is dismissed by stating that Kirschner performed the first successful pulmonary embolectomy in 1924. The fact that Trendelenburg in 1908 conceived the operation and developed its technic on cadavers is not mentioned, nor is it stated that following a number of unsuccessful attempts after the Kirschner operation A. W. Meyer performed several successful pulmonary embolectomies (*Surg., Gynec. & Obst.* 50:891 [May] 1930). To dismiss the subject of ethylene anesthesia with a single line (p. 339), "Ethylene anesthesia in genitourinary surgery was used by Kretschmer (1911)," does not make sense. It does injustice to the physiologist Arno Luckhardt, who discovered the anesthetic properties of the gas, and credits Kretschmer with something to which he never laid claim. Kraske was born, educated, trained and worked all his life in Germany. To place him in Switzerland is an error that could have been avoided by consulting the reliable Fischer. Speaking of Bassini, the author states "Well known also is Bassini's operation for inguinal hernia—an operation done in hundreds of cases daily." Bassini is remembered today only because of his classic herniotomy; whatever other contributions he has made are of no historical importance. This is an example of an error in emphasis.

Finsterer is accorded more than a page, while von Eiselsberg receives five lines. Von Eiselsberg was, of course, a greater surgeon and did far more to advance surgery than Finsterer. The author appears to be much impressed by the number of gastrectomies performed by Finsterer. If that is his criterion, then the palm should go to von Haberer, who, by the way, is mentioned only in passing. As a matter of fact, Finsterer's claim to either originality or priority in the operation for subtotal gastrectomy with an end to side anastomosis is not well founded. This operation was first conceived by von Hacker in 1885 and was first performed by Krönlein. It was elaborated by von Eiselsberg, Roux, von Mikulicz, Delagènière, Doyen and others. In its present form, to which it was brought by Hofmeister, it has been given further application by a great number of surgeons, such as Reichel, Sasse, Polya, the Mayos and Moynihan. The report of 56 cases in which Hofmeister operated can be found in a contribution by W. Burk, one of his assistants (*Beitr. z. klin. Chir.* 76:638, 1911). Finsterer in 1913 advocated a very radical resection of the stomach for the cure of ulcer on the ground that the acidity is reduced thereby, an idea to which we today do not wholeheartedly subscribe. However, the method described by him does not differ in any detail from that of Reichel or of Hofmeister (see "Gastric Resection and Various Methods of Reestablishing the Continuity of the Gastrointestinal Tract," *International Abstract*

of Surgery, Collective Review, February 1926). It would be only fair to call attention to the fact that Emil Rees of Chicago developed independently of and prior to Wertheim the same operation for carcinoma of the cervix uteri with which Wertheim is correctly credited.

In the chapter on American surgery the author includes men whose sole claim to immortality appears to be membership in certain associations or being a secretary or an editor of a surgical publication. It is not argued that these men are not competent surgeons. Competence alone, however, and mastery of ideas and technics developed by others do not entitle one to be mentioned among the makers of surgical history. Only men who have advanced the frontiers of our knowledge in this field are entitled to that unique honor. This is error in judgment as well as bad taste. One begins to wonder whether the author is writing a history or compiling a directory. The name of L. L. McArthur should have been mentioned among the pioneers in the field of appendicitis. Halstead introduced rubber gloves in his operating room not primarily to improve asepsis but because his head surgical nurse could not tolerate powerful antiseptics on her hands. While it is true that Nicholas Senn bequeathed his collection of books to the Newberry Library (p. 315) it is worth noting that the Newberry Library turned the gift over to the John Crerar Library, where the gift is lodged in the Nicholas Senn Room. The service this library is rendering the profession deserves mention.

Finally, it is felt that the illustrations would serve their purpose much better if they accompanied the text rather than being grouped together at the end of the book as a sort of separate chapter.

Family Nutrition. Published by the Philadelphia Child Health Society. Second edition. Paper. Price, 50 cents. Pp. 119, with illustrations. Philadelphia, 1943.

This monograph on family nutrition is a complete treatise. Much of the material is closely set in long lines of relatively small type, which does not make for easy reading. For the student of nutrition, the teacher or the demonstrator, this manual should be exceptionally valuable. It is on too high a scientific level for the vast majority of housewives. Yet it contains much material of great value to precisely this group. The chapter on the dietary value of common foods, and especially the illustrative pages facing the text, is not only informative but is the most readable part of the entire booklet. An excellent feature is the full page bleed-off illustrations and many of the diagrams. Another valuable feature is that beginning on page 70, which shows a week of good meals for children, for boys and girls, for adolescents, for expectant mothers and for various family income groups. As a reference manual for persons capable of using such a device, this publication could be of extreme usefulness in the upper third of homes, where, unfortunately, it is needed least. In fact, to the vast group of nonprofessional persons who make up what is vaguely referred to as "the public" this excellent production would unfortunately remain unappreciated.

The Education of Nurses: Historical Foundations and Modern Trends. By Isabel Maitland Stewart, R.N., A.M., Professor of Nursing Education and Director of the Division of Nursing Education, Teachers College, Columbia University, New York. Cloth. Price, \$3.50. Pp. 399. New York: Macmillan Company, 1943.

Primarily designed for students and educators in nursing, this book presents the progress of nursing education from its ancient origins to the problems it faces in the postwar world. Parallels to the progress and problems of medical education are close: informal instruction preceded the organization of schools, which flourished in numbers if not in quality. There was concern over a supply of graduates, many of them poorly trained, in excess of demands for their services, followed by a decrease in numbers through enforcement of elevated educational standards and improved instruction. The war and its unpredicted casualties then created a shortage, requiring a wisely adjusted balance between unwarranted increases in graduates to serve the new demands and a preservation of such educational standards as would insure adequate care of the sick and injured in wartime and after the peace. The book is written with an imagination that refutes the events of the dead past to the living problems of today and tomorrow.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

MENTAL IMPAIRMENT IN EPILEPSY

To the Editor:—Most of the textbooks teach that epilepsy has much effect on the mind or mental faculties. I seem to recall that some good authority said that the present teaching was that epilepsy seldom affected the mind. Are you able to give me any information on this subject, especially as it affects childhood epilepsy?

Ludwig L. Sogge, M.D., Windom, Minn.

ANSWER.—Approximately one third of epileptic patients seen outside of institutions show some degree of mental impairment, though in only about 10 per cent is this so gross as to be immediately evident. Mental deterioration, when it occurs, is not necessarily the result of the epilepsy. It may be genetic or the result of an antecedent brain injury, of oversedation or of social and intellectual isolation. Various factors may be at work in a given person. The younger the patient when epilepsy begins the graver the prognosis. However, as with adults, various conditions greatly modify the individual outlook. The prognosis is improved if the child had a negative family history of epilepsy or mental disorder, was mentally normal at birth, has no evidence of brain disease, has petit mal (pyknolepsy) or infrequent grand mal and receives proper drug and psychologic treatment. Bibliographies and statistical data on this subject may be found in the following books:

Penfield, Wilder, and Erickson, T. C.: *Epilepsy and Cerebral Localization*, Springfield, Ill., Charles C Thomas, 1942.

Lennox, W. G.: *Science and Seizures*, New York, Harper & Brothers, 1941.

METHYL TESTOSTERONE FOR MYASTHENIA GRAVIS

To the Editor:—Do you have any information on the use of testosterone preparations in the treatment of myasthenia gravis? I have been told that methyl testosterone has been used in this disease because of its effect on creatine and creatinine metabolism.

M.D., Illinois.

ANSWER.—Methyl testosterone has been used in the treatment of myasthenia gravis. Reports on this therapy have not appeared in the literature so far as is known. One clinic has used the drug in the following manner: Fifty mg. has been given each day for a period of two weeks. If no response occurred at that time in the symptoms of myasthenia gravis, the drug was discontinued. At the end of two weeks, if response had taken place, the amount was reduced to 30 mg. a day for a period of four weeks. This was followed by a period of two weeks with a dose of 20 mg. a day. The drug was always taken by mouth. The dosage schedule, as indicated, was set up in an entirely arbitrary manner, there being no way to estimate the amount needed in myasthenia gravis.

One patient, a physician, made a careful observation of his own reactions to this drug. He was well adjusted to prostigmine bromide and therefore was in a position to judge the effect of the addition of methyl testosterone. He was careful, moreover, to control adequately the period of observation, making no change in his way of life. He reports that, after the first forty-eight hours of taking the drug, slow, steady improvement began, which was continued during the subsequent six months. The first effect of the methyl testosterone was a violent peristalsis, indicating that the patient was receiving an overdose of prostigmine bromide. The patient was able to reduce the prostigmine dosage from ten to twelve 15 mg. tablets a day, his maintenance schedule, to about five tablets a day. At the same time he experienced a sense of well-being. When the methyl testosterone was discontinued after a month's trial, he had the most severe exacerbation of his symptoms of myasthenia gravis that he had ever experienced. When methyl testosterone was again given at the end of six weeks, another remission in the myasthenia gravis occurred. In this single case, therefore, the report would indicate that methyl testosterone, when given to patients with myasthenia gravis, tends to cause a remission which lasts as long as the methyl testosterone is taken. One should not conclude, however, that the experiences of this trained observer necessarily mean that similar results would be experienced in other cases. In 4 other cases, moreover, when the drug was used, 1 responded in a similar manner, but in 3 others good effects were not observed.

OVULATION AND PREGNANCY

To the Editor:—When a woman becomes pregnant, does ovulation cease for the duration of the pregnancy? I am teaching a class of nurses and was asked this question. My answer was that I thought ovulation ceased, but I was not positive. I had trouble finding a satisfactory answer in books so am writing you. Further, is it through endocrine action that it ceases, if it does?

M.D., Wisconsin.

ANSWER.—Ovulation probably ceases in women during pregnancy. The main evidence is that: 1. Ovaries removed at operation from pregnant women show no recent corpora lutea nor other evidence that ovulation takes place. It is believed that maturation of the ovum may occur but that this terminates in degenerative changes and atresia. 2. If ovulation did occur in human pregnancy one would think that the ovum so produced would not infrequently become fertilized during the first three months of gestation, when the uterine cavity has not yet become obliterated by the fusion of the decidua vera and decidua reflexa. Under such circumstances it would seem quite possible for the ovum to descend the fallopian tube and embed itself in the decidua vera, thereby giving rise to a second, younger pregnancy, or superfetation. Actually, proved cases of superfetation in the human being are not on record (Studdiford, W. E.: *Am. J. Obst. & Gynec.* 31:845 [May] 1936). 3. In the rabbit a definite physiologic inhibition of ovulation exists during pregnancy. Thus, Snyder and Wislocki (*Bull. Johns Hopkins Hosp.* 49:106 [Aug.] 1931) have found that in the pregnant rabbit the amount of pregnancy urine required to produce ovulation is twenty to forty times that needed in the nonpregnant animal.

This presumable cessation of ovulation during pregnancy is almost certainly endocrine in nature. Two explanations have been advanced: the inhibitory effect of progesterone on ovulation and the action of chorionic gonadotropin, probably through the pituitary, in suppressing ovarian function.

MASKING AND CONTAGION

To the Editor:—"The value of wearing masks in contagion, . . . particularly with reference to epidemic meningitis, tuberculosis, diphtheria and virus pneumonia" (*The Journal*, Oct. 16, 1943, p. 448), merits comment.

Operating room technic demands masking of the nose and mouth because this has proved to reduce sharply the infection of the wound, blocking most of the point blank showering of fresh droplet borne pathogens of healthy carriers from access to relatively unresisting tissues of patients. Contagious precaution technic for diphtheria and virus pneumonia similarly demands masking of all personnel and visitors. It applies also to scarlet fever, measles, influenza, infectious mononucleosis and all such diseases as notably lower resistance, since superinfections complicating them often arise not from the patient's own microflora but from contact carriers' new invasive pathogens. Groups of rheumatic fever convalescents deserve such precautions, and infants should always be so shielded from the common colds of the household. Indeed, the operating room is but one of the places where susceptible exposed tissues are efficiently safeguarded by masking.

Bactericidal aerosol sprays and ultraviolet barriers can be nullified momentarily by the vagaries of air currents, so that they are not to be depended on to protect against the transfer of fresh pathogens as described, or even against all the air contaminants persisting after dispersal and settling or drying of vector droplets. Fine on paper, in practice they stand with sulfonamide prophylaxis in requiring constant toxicologic and bacteriologic checking. They in no way replace the need of masking, which acts right at the source to prevent significant massive inoculums from ever reaching the air, i. e. by air asepsis.

Of course it is never the mask wearer who is being protected. All agree that dried aerial microflora is poorly filtered by any tolerable mask yet devised. Protection for the wearer would have to resemble a gas mask to prevent heavy seeding of the nose and throat of air bacteria transported in tears through the nasolacrimal ducts. Unthinking writers have repeatedly misinterpreted these facts to condemn all masking: they do not realize at all what the proper role of the mask is.

Dangerous respiratory contagions always demand masking during physical examinations and during bedside care, for sick people even when themselves physicians rarely remain so well mannered as not to cough or speak into others' faces. Here the patient must temporarily don the mask, since it works only against the egress of pathogens. Patients having open tuberculosis are unfortunately seldom masked even in teaching institutions. Since most entering students of medicine and nursing are nowadays tuberculin negative and ought to be kept so, such masking as the first step must be enforced to improve the record of occupational tuberculosis morbidity.

Tuberculous patients also benefit by instruction. While they do not learn from usual precepts and pamphlets to lessen gross contamination of air and objects in their surroundings, they do learn readily after they have seen for themselves the insidious spreadings of their own sputum. It is for the physician to dust onto the pharynx a few milligrams of powdered medicinal methylene blue with a clean dried camel's hair brush. A few such applications suffice to teach even an obtuse patient the habits that efficiently keep sputum from reaching most of his close environs (by way of toothbrush, fingers and so on) and that lessen significantly the contamination of air by close range speaking and by open mouthed and unmuffled sneezing or coughing.

Let no one suppose that buying bactericidal gadgets solves the problem, and particularly let no one condemn the aseptic role of masks.

FALCIPARUM MALARIA

THE IMPORTANCE OF EARLY DIAGNOSIS AND
ADEQUATE TREATMENT

HARRY MOST, M.D.
AND
HENRY E. MELENEY, M.D.
NEW YORK

Prior to and since the entry of the United States into the present war, a large number of American civilians have been employed in construction and other occupations in tropical areas where falciparum malaria is endemic or hyperendemic. Already a number of these persons have returned to this country. Some give a history of having had recognized malaria abroad, some have apparently had it in an unrecognized form, and others have become infected en route to America and have come down with acute attacks shortly after their arrival.

Unless one is familiar with the extremely varied clinical picture which falciparum infection may assume and the possibility of the development of alarming symptoms requiring early and intensive therapy, the infection may remain unrecognized and may even terminate fatally. In fact, this tragic circumstance has already occurred among the group dealt with in this report. A striking example of the confusion, difficulties and fatalities which may occur in an area where this disease is not common was seen when physicians in New York City and elsewhere were confronted with the problem of falciparum malaria in drug addicts.¹

Our object in the present report is to review the clinical aspects of falciparum malaria and to emphasize the necessity of keeping this disease in mind when seeing patients with a history of travel or residence in the tropics. Illustrative cases presenting some of the problems in diagnosis are briefly presented, and effective treatment of falciparum infections is outlined.

GENERAL CONSIDERATIONS

The biologic characteristics of *Plasmodium falciparum* are sufficiently different from the other human malarial parasites to be reflected in the peculiar, often bizarre, clinical features and pathology of falciparum malaria. The fundamental differences have been summarized by Kitchen² as follows:

(a) "Internal sporulation." Unlike *Plasmodium vivax* and *Plasmodium malariae*, which undergo development and schizogony in the circulating blood, *Plas-*

modium falciparum completes the latter part of its asexual cycle in the capillaries. The rings grow in the circulating blood for a period of from twelve to twenty-four hours and then disappear into the capillaries, where the parasitized red cells adhere to the endothelial lining of the smaller vessels. Infected red cells also adhere to one another. This frequently results in complete obstruction to numerous capillaries. Predominant localization of such a process in an organ requiring continuous circulation, such as the brain, intestine and heart, readily explains the pathology and clinical disease which one sees in falciparum malaria.

(b) "Marked invasiveness." The potentialities of the parasite density in falciparum infection are limited only by the number of red blood cells. The rapid increase in the number of parasites frequently results in counts as high as two million parasites per cubic millimeter, particularly in fatal cases. This adds to the malignant or pernicious nature of this infection.

(c) "Asynchronicity." The unpredictable and frequently irregular temperature curve which is seen in falciparum infections is probably due to the fact that this parasite is less uniform than the other two human species in the time of completion of its asexual cycle.

CLINICAL ASPECTS

Numerous attempts have been made to classify the various clinical manifestations of falciparum malaria on the basis of the predominant organ or system involved. Such a classification may be useful but can be misleading if one fails to recognize the possibility that the infection may involve several systems with equal severity at the same time.

Predominant Cerebral Involvement.—Stupor and coma are the commonest evidence of nervous system involvement. Convulsions may occur and in some cases have been erroneously ascribed to alcoholic poisoning or head injury. Other neurologic signs, although present in some fatal cases, are not of particular diagnostic aid. Stiffness of the neck, hyperreflexia and pathologic pyramidal tract reflex signs are the most common of these findings. Occasionally intermittent rigidity or sucking and grasping reflexes are seen. Rectal and vesical incontinence are quite common. On the whole, the signs are suggestive of an acute meningitis or encephalitic process.

Mental symptoms are occasionally the outstanding feature of onset and may result in the admission of the patient to a psychiatric institution. The usual finding is confusion, which may be accompanied by restlessness or negativism. Mental symptoms demand immediate intensive parenteral treatment. Such patients must be watched very closely, since they may become manic or commit suicide.

CASE 1.—L. A., a man aged 52, a welder, returned from East Africa to the United States by airplane on Aug. 29, 1943. En route he stopped for a week at Accra, Gold Coast. On arriving in Miami he experienced a chill but continued

From the Department of Preventive Medicine, New York University College of Medicine.

Med. 20:551 (July) 1940; Malignant Malaria Among Drug Addicts. *Epidemiological, Clinical and Laboratory Studies*, Tr. Roy. Soc. Trop. Med. & Hyg. 34:139 (Aug.) 1940.

2. Kitchen, S. F.: The Infection in the Intermediate Host. *Symptomatology, Falciparum Malaria, in a Symposium on Human Malaria*, Publication 15. American Association for Advancement of Science, 1941.

his trip to New York. Two days after his arrival at home he consulted a physician because of upper respiratory symptoms. Coryza was the only physical finding. The temperature was normal, and symptomatic treatment was prescribed. The following day he had a severe chill and could not recognize his wife. He was admitted to the hospital in a deep stupor and could not be aroused even by painful stimuli. His neck was slightly rigid and there was bilateral ankle clonus. There was rectal and urinary incontinence. The temperature was 104 F. Examination of a thin blood film revealed 2,100,000 falciparum parasites per cubic millimeter. Numerous schizonts were found, and many of the monocytes and polymorphonuclear neutrophils contained malarial pigment. The patient received several small doses of quinine sulfate by stomach tube; also a saline infusion and a transfusion. When he was seen in consultation twenty four hours later the blood pressure was 60/40. Intensive quinine treatment by vein was instituted. Infusions and transfusions were continued, but the patient failed to respond and died on September 5, eight days after his first chill. At autopsy all the capillaries of the brain were practically occluded by parasitized red cells.

The presenting symptom when the patient was first seen by a physician was coryza. If a blood smear had been examined at this time, it is probable that the diagnosis would have been established and that intensive treatment by mouth would have prevented the subsequent development of cerebral symptoms. Furthermore, intravenous treatment with large doses of quinine dihydrochloride as soon as the diagnosis was made might have prevented a fatal outcome.

CASE 2.—J. R., a man aged 22, a welder, had been employed in Africa. He arrived in the United States on Feb. 4, 1943 by plane, having stopped at Accra for several days. He had a routine clinical examination in New York on February 8, at which time he had no complaints and there were no objective abnormal findings. His blood was not examined.

The patient first became ill on February 15 in Chicago, with chills, generalized aching, nausea, vomiting, headache and profuse perspiration. A physician found nothing noteworthy on examination except a temperature of 100 F. The provisional diagnosis was grip, and the patient received symptomatic treatment. He apparently improved during the next two days but became suddenly worse on February 18. On admission to a hospital that day he was restless and had a temperature of 104 F. There were no definite physical signs. The white count was 3,500 per cubic millimeter. No parasites were discovered in the thin film. The next day the temperature was normal, but severe headache and nausea continued. A consultant arrived at no definite diagnosis but suggested that typhoid, tuberculosis, leishmaniasis, Chagas' disease, malaria and pneumonia be considered. The next day a thin blood film revealed an overwhelming infection with *P. falciparum*. The patient was delirious and tried to get out of bed. The temperature rose to 104 F., and coma ensued. Two doses of quinine hydrochloride were given intravenously at an interval of eight hours. In addition oxygen was administered and fluids were given by vein. The temperature rose to 107 F. The patient had repeated convulsions and died on February 21, six days after the onset of his illness, three days after admission to the hospital and two days after the diagnosis was established. Specific treatment had been administered only on the day of death.

We have here an example of a person perfectly well on one day and dead six days later of cerebral malaria. At the onset the disease masqueraded as a simple upper respiratory infection. If at this time malaria had been borne in mind, repeated blood examinations by means of thick and thin films would have established the diagnosis and intensive treatment could have been begun early enough to prevent a fatal outcome.

CASE 3.—J. U., a man aged 25, an aeronautic engineer, returned to the United States by plane from India on Oct. 2, 1942. He first became ill on October 10, when he complained of chills and coryza. He perspired profusely and called his physician, who found nothing striking in the examination and considered the complaints related to an upper respiratory infection, for which he prescribed symptomatic treatment. During the next few days the patient complained of severe headache and vomiting. He then suggested to his physician the possibility of malaria as the cause of his illness. Blood smears were positive and the patient was admitted to the hospital. During the next twelve hours he received only 5 grains (0.32 Gm.) of quinine sulfate in sugar coated pills after each meal. When seen in consultation the same day, the patient was delirious. There was slight jaundice, the reflexes were hyperactive and urination was difficult. The temperature was 104 F. Thin blood films revealed *P. falciparum*, approximately 210,000 per cubic millimeter. Gametocytes were moderately abundant and many monocytes contained malarial pigment.

The acute nature of the infection in the face of severe vomiting and pronounced parasitemia with probable cerebral localization indicated the necessity of intravenous treatment. Quinine dihydrochloride was given in doses of 0.6 Gm. every six hours for four doses accompanied by intravenous fluids. Thereafter quinine was given by mouth in doses of 0.6 Gm. every six hours for one week. The patient recovered promptly.

The presenting symptoms were those of an upper respiratory infection. Malaria was not considered until the patient suggested it. The diagnosis was readily established by blood examination. Clinically the patient seemed on the way to developing cerebral manifestations. Treatment when begun was not intensive enough in the face of the high parasitemia. Sugar coated pills are not advisable in the treatment of any form of malaria. Frequently these pills can be recovered in the stool, and one can never be sure that the drug is absorbed. Intravenous treatment with quinine and fluids brought about a rapid recovery.

CASE 4.—E. T., a man aged 22, a college student, returned from Africa to the United States on Feb. 15, 1943 by plane. During the previous year he had been with the American Field Service Ambulance Corps. En route to this country he was held up for four weeks in Lagos, Nigeria, a highly malarious area. He arrived in New York on February 18 and became ill on February 22, when he experienced a severe chill.

His physician immediately examined a thin blood film and found a small number of *P. falciparum* parasites. The temperature was 105.6 F. Two 0.1 Gm. doses of atabrine were administered during the first afternoon. On the following day he received three tablets. The temperature did not fall below 104 F., and he was hospitalized. When seen in consultation the patient was delirious at intervals and confused with regard to time. The temperature was 104.4 F. There was slight icterus of the scleras, and the spleen was just palpable.

Quinine dihydrochloride 0.6 Gm. in 20 cc. of distilled water was administered intravenously and repeated after eight hours. Quinine sulfate by mouth was begun simultaneously in doses of 1 Gm. every six hours for the first twenty-four hours. The following day the temperature was lower and the patient seemed much better. Thin films contained no parasites, but examination of thick drops revealed a few rings of *P. falciparum*. Quinine sulfate 1 Gm. by mouth three times a day was continued for the next two days. The dosage was then reduced to 0.6 Gm. three times a day for the next two days. Further treatment consisted of the administration of atabrine 0.1 Gm. three times a day for seven days followed by plasmochin 0.01 Gm. three times a day. After the second day this had to be discontinued because of severe abdominal cramps and cyanosis.

Although the diagnosis was made at the onset of the patient's illness, treatment was not of sufficient intensity. Atabrine requires a large initial dose in order to attain an effective blood level in a short time. A rapidly developing falciparum infection may get out of hand if this is not recognized. In this case there was no predominant localization of symptoms with the possible exception of the brain, and one can consider it a case of severe general infection. This case also illustrates the occurrence of toxic symptoms from plasmochin in relatively small doses.

Gastrointestinal Involvement.—Gastrointestinal symptoms occur fairly frequently in falciparum infections. These symptoms may vary from mild nausea to intractable vomiting or severe diarrhea. Localized or general pain may occur. Patients have been operated on because of suspected intestinal obstruction or other acute abdominal conditions and have been diagnosed as having had malaria only at autopsy.

The presence of severe gastrointestinal symptoms indicates the necessity for intensive parenteral treatment, both specific and supportive.

Diarrhea may be particularly misleading in persons recently back from the tropics. Bacillary and amebic dysentery should be considered, but malaria must first be excluded. If parasites are found, specific treatment will result in a prompt cure of the diarrhea.

CASE 5.—P. C., a man aged 36, returned from Africa to the United States on May 19, 1942. He had been to Africa on numerous occasions to collect animals for zoological gardens and had had numerous attacks of malaria. He arrived in Boston and had a chill with pain in the chest. He was seen by a physician, who thought he might have pneumonia and advised hospitalization, but this was refused because he was in charge of a cargo of animals. The following day he suffered from severe diarrhea and vomiting and had another chill with a temperature of 104 F. He went to New York on May 21. He was seen in consultation, and blood examination showed 60,000 falciparum parasites per cubic millimeter. He was immediately hospitalized. On admission his temperature was 104.6 F. He continued to vomit and was definitely jaundiced. Three 0.6 Gm. doses of quinine dihydrochloride were given intravenously at six hour intervals. The patient's stomach was washed out and 2,000 cc. of saline solution with 5 per cent dextrose was given intravenously. After twenty-four hours the vomiting and diarrhea had stopped, the temperature was normal and the patient appeared much better. Quinine sulfate was then given for two days by mouth in doses of 1 Gm. three times a day after meals. A course of atabrine followed consisting of 2.4 Gm. during the next seven days. Finally, plasmochin 0.01 Gm. three times a day was given for five days.

With a history of numerous previous attacks of malaria and the patient's recent arrival from Africa, malaria should have been considered as a strong possibility even though his first localizing symptom was pain in the chest. Subsequently the predominant clinical manifestation was gastrointestinal.

CASE 6.—A. B. arrived in New York on Aug. 29, 1943 by plane from Africa. En route he remained at Accra for one week. He first became ill on September 6, when he complained of generalized aches, profuse perspiration and a severe chill. When he was seen by his physician the following day, his temperature was 103 F. The only physical finding was herpes labialis. He was placed on sulfadiazine. The following day he began to vomit and had another chill. The physician considered the possibility of malaria at this time and ordered quinine 0.3 Gm. three times a day. He was admitted to the hospital the following day. When seen in consultation he was acutely ill. The temperature was 101 F., and there was moderate icterus of the scleras. The tongue was brown

and dry, and the spleen could be felt easily. The urine contained bile and increased urobilinogen. Examination of thin and thick blood smears revealed no parasites, but many of the monocytes and polymorphonuclear neutrophils contained malaria pigment. Since neither atabrine nor quinine for intravenous use was available and the patient had ceased vomiting, he was given quinine sulfate in capsules 1 Gm. three times a day for two days. Atabrine was then available and was administered in doses of 0.2 Gm. every six hours for five doses followed by 0.1 Gm. three times a day for six days, making a total of 2.8 Gm. Supportive treatment consisted in the liberal administration of intravenous saline solution and dextrose.

In this case severe vomiting and jaundice were outstanding. Specific treatment was not begun until the fourth day of the disease. It is interesting that after two days of sulfadiazine therapy and 2 Gm. of quinine no parasites could be found. It is known that sulfadiazine is partially effective in temporarily lowering the parasite density in *P. falciparum* infections. Probably the use of this drug followed by small doses of quinine accounted for the failure to find parasites in the peripheral blood.

CASE 7.—P. M., a contract engineer, arrived in Miami on March 26, 1943 by plane from Africa. On the same day he had severe chills, fever, vomiting and diarrhea. Hospitalization was suggested, but the patient proceeded to New York. He was seen in consultation on April 2 and stated that while in Africa in May 1942 he had had recurrent attacks of chills, fever and vomiting, for which he had been hospitalized several times. At no time were malarial parasites found in thin films. On one occasion his illness was believed to be prostatic disease.

On physical examination no striking abnormalities were noted. The temperature was 102.6 F. Examination of thick and thin films revealed *P. falciparum* rings and gametocytes. The patient was hospitalized and received quinine sulfate by mouth 1 Gm. three times a day for three days, then 0.6 Gm. three times a day for four days. He was then placed on atabrine 0.1 Gm. three times a day for seven days, followed by plasmochin 0.01 Gm. twice a day for five days. His temperature became normal on the second day and remained so throughout his stay at the hospital.

This patient stated that he had been born and raised in rural Tennessee and had been told that he had malaria as a child. Perhaps he had some immunity, since he was able to control his infection without treatment for a considerable length of time. The symptoms which this patient experienced for approximately eleven months were probably due to malaria, since they all promptly disappeared following treatment.

This case indicates that falciparum malaria may simulate a chronic infection of the urinary tract and then assume an acute stage.

Blackwater Fever.—This is the term applied to the clinical syndrome resulting from spontaneous intravascular hemolysis of red cells occurring in falciparum malaria. The mechanism of its induction is unknown, but it appears that red cells from blackwater fever patients have an increased fragility to lysolecithin, although their fragility to saline solution is normal. Normal red cells transfused into a patient with blackwater fever are destroyed just as readily as the patient's own cells, suggesting the presence of some circulating hemolysin. Predisposing factors seem to be continued residence in hyperendemic areas, numerous reinfections and incomplete and intermittent treatment. Precipitating causes are chilling, pregnancy, acute infections, trauma and quinine.

The outstanding clinical feature is the passage of dark red, brown or black urine containing oxyhemoglobin

and methemoglobin. In severe attacks jaundice, anemia and azotemia, and anuria occur. In mild attacks, however, abdominal and loin pain may be slight and clinical jaundice absent. Death may result early in the attack as a result of anoxia or later as a result of complete urinary suppression.

Blackwater fever occurs more commonly in hyperendemic areas of falciparum malaria. Occasionally a case is seen in the United States, but in most cases seen in this country the disease was acquired in the tropics and the attack follows shortly after arrival in a nonendemic area. One must therefore assume that hemoglobinuria in patients who have recently returned from the tropics is due to falciparum malaria. Blood examination cannot be depended on for diagnosis, because parasites sometimes cannot be found during the acute attack.

CASE 7.—C. L., a white man aged 20, was removed from the Seamen's Home in New York City to the psychiatric division of Bellevue Hospital because he was confused. On admission the patient stated that he had been sick for four days with chills, pain in the abdomen and flanks, nausea and vomiting. He had been in South America three weeks previously and thought that he had malaria on several occasions for which he had taken quinine intermittently but not during the past few months. The patient was apathetic and restless. His temperature was 103 F. There was pronounced costovertebral tenderness on both sides. Blood smears contained numerous rings of *P. falciparum*. The urine was dark red and contained large amounts of oxyhemoglobin and methemoglobin. Subsequent specimens varied from deep red to brown and almost black. He received several blood transfusions and large amounts of fluid intravenously. In addition he received atabrine by mouth in doses of 0.2 Gm. three times a day for the first three days and then 0.1 Gm. three times a day for five additional days. He became afebrile, and the urine returned to normal. He was discharged from the hospital thirteen days after admission.

In this case blackwater fever occurred either in the course of a recently acquired falciparum infection or during an early relapse. Prompt supportive treatment in the form of fluids and whole blood was successful in tiding the patient over during his period of intravascular hemolysis. Specific treatment against his malarial infection consisted of 3.3 Gm. of atabrine given in the course of a week.

Algid Form.—Occasionally one sees in acute falciparum infections a so-called algid variety. The patient collapses suddenly and presents the picture of medical shock. He may be afebrile. Unless one considers the possibility of malaria in this condition and institutes heroic treatment immediately, the patient usually dies within a short time.

DIAGNOSIS

The diagnosis of falciparum malaria depends essentially on finding the organisms in the blood and the identification of the species. Thin smears require proper staining, which should be heavier than is necessary for differential white blood cell counts in order to avoid missing the ring forms. A single negative thin film should never be depended on to exclude the diagnosis. Col. D. K. Lindsay³ has aptly said "A negative blood slide has sent many to the grave." If necessary, smears should be repeated at intervals of twelve to twenty-four hours to insure discovery of parasites. In blackwater fever parasites may not be found at all during the acute attack. The examiner must be able to differentiate between malaria parasites,

platelets, bacteria and other artefacts. In heavy infections monocytes and neutrophilic granulocytes may contain malaria pigment even in the absence of parasites. This is diagnostic and indicates a serious infection.

Thick drop preparations should be employed in every case in which the thin film is negative. In fact, every laboratory technician should be acquainted with the thick drop technic, and physicians should employ it routinely.

The characteristics of *P. falciparum* parasites as they appear in the peripheral blood must be borne in mind. Early in the infection one usually finds only the ring forms. These are usually small delicate rings and are frequently implanted at the margin of the red cell. Multiple infection of a single red cell is common. Double chromatin dots often occur and frequently are found at opposite poles of the ring. After the first week of symptoms one may also find the characteristic crescentic gametocytes. Thus in falciparum infections one usually finds only rings or gametocytes or both. In overwhelming infections, especially if the patient is in shock, one may find schizonts in the peripheral blood. The presence of malaria pigment in white blood cells is suggestive of heavy falciparum infection.

Clinically malaria should be suspected in any person with any complaint whatever if he has recently returned from the tropics. As has already been pointed out, the clinical manifestations may not be suggestive of malaria at all, and if one waits for the development of characteristic chills and fever it may be too late to begin successful treatment. Fever may be entirely absent even in overwhelming infections, and when fever does occur the temperature curve may not follow the usual pattern which we commonly associate with malaria. The white blood cell count or differential formula is not a reliable aid to diagnosis. We have seen white counts which were as low as 3,250 and as high as 46,000. Monocytosis may not be increased. Anemia may not have developed or may be very severe with the red count between 1 and 2 million. On the other hand, in overwhelming and even fatal infections there may be no evident anemia. Splenomegaly is not a constant finding in acute falciparum infection. When it does occur, enlargement does not reach the proportions which is usually seen in vivax malaria. Frequently even when the spleen is considerably enlarged, as demonstrated at autopsy, it may not be felt during life, possibly because it is very soft.

Thus it can be seen that it is impossible to present a clinical description of falciparum infection which will cover all its manifestations. The diagnosis can be made only if it is kept in mind and if suitable steps are taken to confirm it.

TREATMENT

In the treatment of falciparum infections it is very essential to start early and to use suitable drugs in sufficient dosage to insure an early and effective plasma concentration. An excellent statement on treatment can be found in Circular Letter 153 from the Surgeon General's Office, published in *THE JOURNAL*, Sept. 25, 1943,⁴ and every physician is advised to keep this statement on hand for reference. All physicians should make sure that the hospitals in which they work have on hand atabrine hydrochloride in tablets for oral use and in ampules for intramuscular injections, and

3. Lindsay, D. K.: Guidance Notes on Pernicious Malaria, *Tr. Roy. Soc. Trop. Med. & Hyg.* 37: 63 (July) 1943.

4. The Drug Treatment of Malaria, Suppressive and Clinical, circular letter no. 153, Office of the Surgeon General, U. S. Army, *J. A. M. A.* 123: 205 (Sept. 25) 1943.

quinine dihydrochloride in ampules for intravenous use. Frequently small hospitals and rural pharmacies do not have these drugs on hand, and valuable time is lost in procuring them.

For the oral treatment of falciparum malaria physicians must depend almost entirely on atabrine. This drug, if properly used, is as effective as quinine by mouth in controlling infections, and its toxicity is minimal. It must be borne in mind that the drug is an acridine dye and frequently produces a yellowish discoloration of the skin, but this is not a sign of toxicity and is not an indication for altering or suspending treatment. The discoloration disappears a few weeks after cessation of treatment.

Totaquine (U. S. P. XII), a crude extract of the crystallizable alkaloids of cinchona, is advocated and is becoming available as a substitute for quinine in oral medication. It is effective in doses 50 per cent larger than those advocated for quinine. It should be used, however, only in vivax and malariae (quarant) infections and in mild or chronic falciparum cases.

Treatment of Uncomplicated Infections.—In the treatment of mild uncomplicated falciparum infections atabrine by mouth is recommended. During the first twenty-four hours two tablets of 0.1 Gm. each are given every six hours for five doses, making a total of 1 Gm. in the first twenty-four hours. Gastrointestinal symptoms are largely avoided if the drug is given with food or sweetened fluids. Following this, one tablet of 0.1 Gm. should be given three times a day after meals for at least six days, making a total of 2.8 Gm. in seven days.

If the patient cannot take atabrine, totaquine may be used in doses of 1.5 Gm. three times a day after meals for three days, followed by 1 Gm. three times a day for four days. In some hospitals or pharmacies quinine sulfate may still be available in small amounts for the treatment of malaria. If no other drugs are available or if atabrine cannot be tolerated, quinine sulfate in capsules or disintegrating tablets can be given. The initial dose for the first three days should be 1 Gm. three times a day followed by 0.6 Gm. three times a day for at least four days. Quinine should never be given in sugar coated pills. Rapid absorption may be assured by the addition of a few minims of dilute sulfuric acid to each dose of quinine.

Treatment of Complicated Infections.—In the presence of complications, such as vomiting, diarrhea or manifestations of central nervous system involvement, or in infections in which the parasite density is 50,000 per cubic millimeter or more, atabrine dihydrochloride should be given intramuscularly in solution, 0.2 Gm. in each buttock, making an initial dose of 0.4 Gm. This can be repeated for an additional one or two doses at six hour intervals. Treatment by mouth should be started as soon as the patient can retain oral medication. The dosage schedule should be such that the combined amounts from parenteral and oral therapy total 1.0 Gm. during the first twenty-four hours. Subsequent treatment consists of 0.1 Gm. three times a day after meals until a total of 2.8 Gm. has been given in one week. If atabrine is not available for parenteral use and the patient requires parenteral treatment, quinine dihydrochloride should be used intravenously. The initial dose should be 0.6 Gm. in an infusion of 200 cc. of 5 per cent dextrose in isotonic solution of sodium chloride. Quinine by vein should always be administered very slowly, since rapid injection may produce a definite fall in blood pressure. In high

concentrations given quickly it may act as a direct cardiac poison. Epinephrine solution 1:1,000 should be on hand and if collapse occurs 1 cc. should be given intravenously. Intravenous therapy may be repeated every four to six hours until the patient is clinically well enough to continue medication by mouth. If at this time atabrine is available, 1 Gm. is administered during the first twenty-four hours in five divided doses of 0.2 Gm. each followed by 0.1 Gm. three times a day for six days. If atabrine is not available as soon as clinical improvement warrants oral therapy, quinine sulfate 1.0 Gm. or totaquine 1.5 Gm. in capsules should be given three times a day after meals for three days and then quinine sulfate 0.6 Gm. or totaquine 1 Gm. three times a day for four additional days.

Treatment of Comatose Patients.—Quinine dihydrochloride 0.6 Gm. should be given intravenously every four hours until it is evident that the patient is no longer critically ill. Atabrine is then begun in the manner already prescribed so that 2.8 Gm. is given in seven days. Spinal drainage may restore the patient to consciousness and should be performed. Fluids by vein should be administered freely so that the specific gravity of the urine is 1.010 or less. There is evidence that nicotinic acid (not nicotinic acid amide) produces dilatation of cerebral capillaries and increases cerebral blood flow.⁵ It seems rational to include 100 mg. of nicotinic acid in the infusion containing each dose of quinine dihydrochloride to facilitate the penetration of the drug to the parasitized capillaries in which the effective lumen is reduced. If necessary nicotinic acid may be given intravenously every hour to maintain cerebral capillary vasodilatation. In 1 case this procedure restored consciousness immediately.

Treatment of Blackwater Fever.—Steps should be taken to prevent the precipitation of acid hematin, which may result in anuria. Sodium bicarbonate should be given, by mouth if possible, to maintain an alkaline urine. If necessary it may be given intravenously in the form of an infusion of 500 cc. of a 2 per cent solution in isotonic solution of sodium chloride. If anemia is severe or if the initial hemolysis produces severe anoxia, repeated transfusions of whole blood are indicated. Dextrose or plasma should be given freely to maintain a normal water balance and to stimulate urinary output. If parasites are present in the peripheral blood, atabrine is advised in the dosage already given.

Symptomatic Treatment.—This should include steps to insure restoration of salt and water metabolism to a normal state. In the presence of vomiting, the stomach may be washed out and subsequently liberal amounts of 5 per cent dextrose in isotonic solution of sodium chloride given intravenously so that the specific gravity of the urine is not above 1.010. If anemia is very severe, blood transfusions may be resorted to. In all cases of anemia, iron in the form of ferrous sulfate 0.3 Gm. three times a day after meals should be given as soon as possible.

INSTRUCTION OF PERSONS RETURNING FROM THE TROPICS

Every passenger and crew member of an airplane returning from a malarious region should be instructed to obtain medical attention on the first development of

5. Aring, C. D.; Ryder, H. W.; Roseman, Ephraim; Rosenburt, Milton, and Ferris, E. B., Jr.: Effect of Nicotinic Acid and Related Substances on the Intracranial Blood Flow of Man. *Arch. Neurol. & Psychiat.* 46: 649 (Oct.) 1941. Loman, Julius, and Myerson, Abraham: Alcohol and Cerebral Vasodilatation, *New England J. Med.* 227: 439 (Sept. 17) 1942.

any symptoms of illness, even those of a common cold. Such instruction should be the responsibility of the steward on the plane. It can be accomplished by presenting to each passenger and crew member a card of convenient size carrying a carefully worded statement that he has probably been exposed to infected mosquitoes, that the disease may develop in a serious form within a few days or weeks, that the symptoms may be indefinite, and that he should have a physician examine his blood for malaria on the first appearance of any symptoms. Airplane companies and military departments should realize their responsibility for preventing fatalities from malaria and should be urged to provide such instructions for early diagnosis.

SUMMARY

Physicians throughout the United States may be confronted with the diagnosis and treatment of civilians recently returned from the tropics. Unless malaria is considered as a possibility in every case no matter what the symptoms, the disease may be overlooked and may progress to a point at which treatment is of no avail.

Every patient returning from the tropics should have a thick and thin blood smear examined for malarial parasites, and if negative this should be repeated every twelve to twenty-four hours until malaria is confirmed or excluded.

If the diagnosis of malaria is not made but the condition of the patient progresses unfavorably, specific treatment for malaria should be instituted. Such treatment should not interfere with other diagnostic procedures, cannot hurt the patient and may prevent fatalities. Search for parasites should be continued.

The clinical manifestations of falciparum malaria may not follow any given pattern. The symptoms of onset are most frequently mistaken for infections of the upper respiratory tract and various gastrointestinal disorders. Severe vomiting or diarrhea and signs or symptoms of cerebral involvement require intensive parenteral treatment.

Atabrine by mouth is recommended in all uncomplicated falciparum infections.

In cases of severe parasitemia or evidence of visceral localization, atabrine should be given intramuscularly or quinine intravenously. Such treatment must be started early and continued with intensity until there is sufficient clinical improvement to warrant changing to treatment by mouth.

In coma or predominant cerebral localization, quinine dihydrochloride should be given intravenously every four hours with dextrose solution and isotonic solution of sodium chloride. Spinal drainage may be useful in restoring consciousness. Nicotinic acid intravenously is recommended to produce dilatation of cerebral capillaries.

Only serious consideration of the possibility of malaria in illnesses occurring among patients with a history of recent residence or travel in the tropics and early intensive treatment will prevent serious complications and fatalities.

Passengers and crew members of all airplanes returning from malarious regions should be warned to obtain a blood examination for malaria at the onset of any illness.

477 First Avenue.

PRODUCTION OF BLOOD DERIVATIVES TO MEET WAR REQUIREMENTS IN GREAT BRITAIN

WITH A NOTE ON THE LARGE SCALE
PREPARATION OF A DRIED PRODUCT

R. I. N. GREAVES, M.B., B.Ch.
LONDON, ENGLAND

In a country at war the choice of a blood substitute and its preparation must be considerably influenced by the special circumstances of the moment. The present review describes briefly the various phases through which this subject has passed during the last four years and the position reached at the present time.

With the return of peace it may well be that many different blood substitutes will be brought forward, but the assessment of their relative merits will entail much clinical trial and experience.

Stored whole blood has but a limited life and therefore cannot be made universally available; moreover, there are certain conditions such as burns in which the circulatory volume is reduced without a corresponding reduction in the number of red cells and in which a transfusion containing red cells may not be beneficial. Certainly in war and probably also in peace there is a definite need for a stable "blood" substitute which will restore and maintain the blood volume. Intravenous saline solution has long been used and, though in some instances its effects have been dramatic, its failing is that the injected crystalloid rapidly diffuses into the tissues and so the beneficial effect is but transitory. For this reason infusions of saline solution and acacia were introduced during the last war because the colloid osmotic pressure exerted by the acacia rendered the beneficial effects of the saline solution more lasting. But apparently the acacia was not removed from the body and there is some evidence that the retained acacia may lead eventually to liver damage.

Nature's method of retaining fluid in the circulation is by the colloid osmotic pressure exerted by the plasma proteins. Animal plasma protein is readily available in ox and horse plasma, but these proteins are foreign to man and their use involves all the problems of the sensitization of the individual.

Early in 1940 it was appreciated from the work of American observers that human plasma and possibly serum might meet the urgent demands which were being made for a blood derivative. Since in England it is essential to maintain large blood banks owing to the possibility of many air raid casualties occurring in any part of the country, human plasma is available in large amounts as a waste product from such banks.

It is essential that the blood derivatives should be really stable and free from infection. Liquid unfiltered plasma or serum is undoubtedly more stable than whole blood, but on storage the plasma tends to clot and both throw down a flocculent precipitate. This instability is moreover accentuated by the shaking which occurs during transport and by fluctuations in temperature. Shaking can be minimized by filling the bottles completely, but storage in equitable temperatures is not practicable under service conditions. Further, both plasma and serum are excellent culture mediums and the odd organism which may escape detection on routine bacteriologic examination will multiply to formidable proportions before the bottle is used. This is a real danger,

From the Drying Unit of the Medical Research Council.

since detection of infection by naked eye inspection, which is the only method available to the clinician, may prove difficult in a material which is normally opalescent and in which precipitation naturally occurs.

Sterility could, on theoretical grounds, be ensured by the addition of an antiseptic such as merthiolate, but Mackay¹ has shown that no antiseptic is available at present which, if used in sufficient strength to assure sterility, might not be considered dangerous to the patient who received a large infusion of such a fluid.

The danger of infection is greatly reduced, though not eliminated, by Seitz filtration. After a short trial of unfiltered plasma, workers in England insisted that liquid serum or plasma should not be used unless it had been Seitz filtered, since Seitz filtration gave a clear fluid in which any cloudiness or precipitation due to infection could be detected. Further, there was some evidence (which has since been proved to be incorrect) that if the icogenic factor was present it might be removed by Seitz filtration. Clinicians were instructed not to use liquid serum or plasma which was cloudy or showed a precipitate. This, while eliminating the danger of giving infected material, had the result that after a few months storage all the material was returned to the blood depots because of the natural precipitation which inevitably occurred. Seitz filtration, though essential from the point of view of sterility, introduced a major difficulty in the preparation of plasma, for it adversely affects its stability and leads to clotting.

At the beginning of the war there was much controversy over the relative merits of serum and plasma. Those who favored plasma claimed that serum was toxic, citing the experiments of Brodie² on the injection of homologous serum into cats; they also stated that the absence of fibrinogen might result in serum being a less valuable fluid than plasma. Owing to the difficulties encountered in filtering plasma, and since at that time it was essential to produce a blood product rapidly and in quantity, large amounts of filtered serum were used and the expected fears were not realized clinically. Nothing simulating the Brodie phenomenon has been observed in man. Reid and Bick³ have shown that serum and plasma tend to possess smooth muscle contracting substances and that normally serum contains these factors in larger amounts than plasma. It is not clear that clinically these factors may not have their value, but experiment has shown that these pharmacologically active substances are minimal in serum if the serum is prepared by clotting plasma or in clotted whole blood if the clots are kept cold and separation and Seitz filtration are carried out as speedily as possible. Those who favor serum cite the difficulties of filtration, the instability and dilution of filtered plasma and the possible harmful effects of the citrate.

If plasma is to be collected, 420 cc. of blood is drawn into 120 cc. of dextrose citrate solution. If the bottles are allowed to stand in the cold room the cells sediment and about 250 cc. of plasma can be siphoned off; this represents about 14 Gm. of protein in a 5.6 per cent solution. The yield is not greatly increased by centrifuging the bottles but can be increased by the use of the alpha Laval separator; the use of this separator is, however, restricted to fresh blood, for blood which has been stored for more than three days is grossly hemolyzed by this procedure.

If serum is required, 540 cc. of blood is collected in a dry bottle, the blood allowed to clot and the serum poured or siphoned off, giving a yield of about 40 per cent, or 215 cc. of a 7 per cent protein solution or 15 Gm. of protein. Thus, since one can bleed more into the standard bottle when dry, in spite of the lower yield, actually more protein can be obtained from the donor who is bled for serum.

The serum or plasma is separated into 2 liter pools, all groups being mixed. A bacterial count is done on these pools prior to filtration; theoretically no contaminated pool should be used, but as a wartime measure material containing less than 100 organisms per cubic centimeter is accepted provided it does not contain pathogenic organisms. The fluid is next clarified through a cotton pulp filter and then passed through a Seitz filter press. If the material is serum, this offers no difficulties; but plasma will clot unless special precautions are taken.

The first method of overcoming this difficulty with plasma was the rapid filtration method of Macfarlane and his collaborators.⁴ This method up to a point was satisfactory but was wasteful in filter pads, and the filtered material was liable to undergo delayed clotting particularly if kept in the cold. To overcome this the "alkali wash" method was introduced by Bushby, Buttle and Whitby.⁵ This method undoubtedly achieved its end but was clumsy to operate and if, after washing through the filter, the plasma was collected too soon serious dilution occurred; if too late there was serious wastage of plasma. This method as carried out by different workers met with varying success. Bushby and Whitby⁶ then introduced the "alkali" process; this method is undoubtedly simpler than the "alkali wash" method, but the material is very liable to precipitate especially on transportation, and there appears to be some alteration in the plasma proteins.

Liquid serum and plasma were both used successfully in the raids of 1940-1941, but they were not ideal products for the reasons mentioned. Many attempts have been made to produce a more stable liquid, of which the most successful in this country has been the low temperature ether extraction method of Macfarlane;⁷ after this process a beautifully clear product results which has lost its lipoids and which remains clear from clouding and precipitation for some months—the actual time awaits the results of observation now in progress. Moreover, if plasma is treated by this method the fibrinogen is removed, so that filtration can be effected without the risk of clotting.

Where it has been possible to hold the liquid material in the frozen state this method has been tried, but even in warm water the bottles take at least half an hour to thaw, and when the supplies are wanted in a hurry this is too long a period; moreover, under war conditions it may be that all forms of heat have been cut off by bombing, in which case the material will not be available for several hours and this slow thawing will then cause the precipitation of fibrin in the plasma—an accident which would also occur following any prolonged refrigeration failure. This method, therefore, has found little favor.

Though liquid serum and plasma are unstable, in the dry form they appear to be completely stable and can be transported anywhere and stored in any climate; moreover, if required the dried product may be reconstituted in a concentrated form.

The dry product has the disadvantage that there is no decrease in its bulk; in fact, as the solvent has also

Fig. 1.—General view of the desiccator room, showing the secondary desiccators in the foreground and the primary desiccators with the loading staging in the background. The heater heads from the two chambers which are defrosting are raised.

to be transported the bulk is actually increased; moreover, the extra manipulation of making up the dried product, although it occupies only half a minute, is a disadvantage. On solution also the dried product is cloudy, owing to an alteration of the lipid distribution. This can be avoided by a preliminary low temperature ether extraction, but since clinically this cloudiness seems to be of no significance the extra complication of the ether extraction would not appear to be justified as a wartime measure, though obviously in peacetime the elegance of the preparation would justify the extra cost and complication of the process.

Although liquid serum and plasma were extensively and successfully used for civilian casualties, on account of their instability they were less satisfactory for the services, which therefore had to have priority on the limited supplies of the dried product that were available. The advantages of a really stable product were, however, so great that further drying facilities were made available, and now it may be said that in this country they are probably sufficient to meet the day to day demands of the war situation both for the services and for the civilian population. The time has come, therefore, to consider whether technical methods should not be developed which would allow plasma and serum to be dried without filtration, and this possibility is being borne in mind. Conditions might arise, however, when for a short period at any rate the drying facilities could not meet the demands which would then have to be met by the issue of liquid material. It is thus still important from the point of view of the war effort that experiments on the production of a stable liquid product should continue, apart from their intrinsic interest as a problem in protein chemistry.

It is probable that experience in blood banking methods will lead to a great decrease in the amount of time expired blood that is turned over to the processing plants, and that in order to meet the demands for a blood derivative donors will be bled specifically for this purpose. Since a really satisfactory method for filtering plasma still remains to be found, the tendency in this country is already to keep the amount of waste blood

bank plasma to a minimum and to bleed donors for serum to meet the need for a blood derivative. In this way the advantages that serum has when compared with plasma, namely a higher protein content, no added chemicals and ease of filtration, can be utilized. Owing to the shortage of supplies and of skilled personnel, no attempt has as yet been made in this country to produce purified albumin by the alcohol method of the Harvard group, nor has any attempt been made to find substitutes for human protein such as bovine albumin, gelatin, isinglass, pectin or casein hydrolysates.

THE DRYING OF SERUM AND PLASMA

The drying plant at present operated by this unit is based on the experimental model of Greaves and Adair⁸ and on the experience gained with several similar plants of intermediate size. The capacity of the plant is 2,500 bottles each containing 400 cc. per week; provision is made for doubling this output if required.

The bottles of liquid serum or plasma first have their metal caps removed, and these are replaced by a special "drying cap." These consist of a layer of cotton wool between two layers of muslin fixed over a perforated metal cap with a steel ring. These caps will allow the passage of water vapor but prevent the entry of bacteria into the bottles. Thus if this change of caps is carried out with sterile precautions the bottles can be taken through the whole drying process without risk of contamination. The bottles after capping are placed in a cold room at $+2^{\circ}\text{C}$. to precool over night.

The next day the bottles are "spun frozen."⁹ In this process 108 bottles at a time are spun on their vertical axes at a speed of 900 revolutions per minute in a cold room maintained at -18°C . Under these conditions a cone is forced down through the fluid, which is flung to the periphery of the bottle, where it freezes, thus exposing a maximum surface for evaporation during the drying process together with a minimum depth of frozen material. Under these conditions the plasma freezes with a very small crystal size, and this has the effect of making the dried material extremely rapidly

Fig. 2.—General view of desiccator room, showing the drying control panel on the right.

soluble, the solution time of the dried product being less than half a minute.

The "spun frozen" bottles are then transferred to a storage room maintained at -25°C . This room has a capacity for storing 5,000 bottles, or fourteen days'

supply, and so acts as a buffer between fluctuating supplies and the drying plant.

The drying apparatus consists of eight steel vacuum chambers 3 feet in diameter by 6 feet high. In the bottom of each chamber is a steel coil through which brine cooled to between -41 and -44 C. is circulated. The lid of each chamber has attached to it a nest of 180

Fig. 3.—View of the engine room showing the two automatic compounded ammonia refrigerator compressors

tins into which the bottles fit, and round each tin is an electric winding used for heating the bottles during desiccation. The amount of heat used, $1\frac{1}{4}$ kilowatts per chamber, is regulated so that the drying cycle takes three days. Thus two chambers are loaded and two chambers are unloaded each day.

The eight chambers are connected by a common manifold to two 3 horsepower single stage vacuum pumps; these pumps are backed by small single stage pumps. During evacuation of a chamber both pumps are used, but after this one pump will maintain the six chambers which are in operation at a vacuum of 0.15 mm. of mercury (Pirani).

In each chamber is a control bottle containing a thermocouple which records the temperature of the material being dried. During loading and evacuation the temperature of the serum rises to -20 C., but once the critical vacuum (about 1 mm. of mercury) is passed the temperature starts falling, owing to the latent heat of evaporation of the ice. When the temperature reaches -30 C., heating is started and the temperature rises to -22 C., where a state of equilibrium is obtained till the material is nearly dry. At this stage the temperature starts rising, and when the plasma is dry this temperature is allowed to rise to $+30$ C. at which it is maintained thermostatically.

On unloading, the evaporated water is found as ice on the refrigerated coils at the bottom of the desiccator, this ice is thawed by circulating heated brine through the coils, the water is removed and the dry chamber is made ready for reloading the next day.

On removal from these primary chambers the dried material contains 0.4 per cent of its dry weight of residual moisture. This is removed by placing the bottles in a secondary desiccating chamber in a high vacuum over phosphorus pentoxide for two days. After these two days of further desiccation the bottles are removed and their drying caps replaced with a rubber washer covered with a screw-down metal cap which has a small hole punched in its center; a sterile hypodermic needle plugged with cotton wool is then stuck through the hole in the metal cap and the rubber washer, and the bottles are returned to the secondary desiccators

for a further two days desiccation in vacuum. About 1 Gm. of phosphorus pentoxide is required for each bottle for the whole of this secondary stage desiccation. Finally the vacuum in the secondary chambers is replaced with pure dry nitrogen to a slightly positive pressure; the chambers are then opened and the needles pulled out of the bottles, which are now absolutely dry and packed in pure dry nitrogen. The holes in the metal cap and the rim are now sealed with plasticine and the bottle neck finally dipped in a "Perspex" lacquer to give a hermetic seal.

Thus each bottle takes seven days to go through the whole drying cycle, and the output is 360 bottles per day or 2,500 bottles per week. Provision is made to double this output, if required, by running a shorter schedule.

Refrigeration is required for the drying chambers, the spinning room and the storage room. This is provided by circulating cold brine from a common tank maintained at between -41 and -44 C. by two compounded ammonia compressors. Normally one compressor can balance the whole load, the other acting as a reserve standby.

In the event of a prolonged mains failure, which has to be considered in wartime, a petrol motor is arranged to operate one of the vacuum pumps and another petrol motor will operate the pump circulating the brine through the primary desiccators. With a store of 6 tons of cold brine in the tank, it is estimated that the mains would have to fail for longer than twenty-four hours to cause any serious difficulty.

An alarm system operates in the event of a mains failure, if the brine temperature rises to -40 C. or if the vacuum rises to 0.2 mm. of mercury (Pirani). When the alarm system operates, all heater circuits are immediately switched off automatically. This alarm system has proved a great saving in manpower, since only one person need be on duty at night; and, since he can sleep, he is able to work the next day. In fact, it has been one of our main considerations in designing this plant that it should require a minimal personnel

Fig. 4.—The freezing room, showing the apparatus for "spin freezing," 108 bottles each containing 400 cc. of fluid. The fan in the background circulates the air over the freezing unit, which is behind the diaphragm, maintaining the temperature of the room at -18 C.

to operate it and, by making the plant simple and automatic, the staff for continuous running seven days a week has been kept to five men, three skilled, two semiskilled; one mechanic on half time, and eight unskilled women. Since it requires just less than 2 units of electricity to freeze, store and dry each bottle, the process is cheap to run.

PROSTATIC CARCINOMA TREATED BY ORCHIECTOMY

A SECONDARY REPORT BASED ON SEVENTY-FIVE
CASES OBSERVED FOR AT LEAST TWENTY-ONE
MONTHS FOLLOWING OPERATION

REED M. NESBIT, M.D.

AND

ROBERT H. CUMMINGS, M.D.

ANN ARBOR, MICH.

Fifteen months ago a follow-up study was conducted on 75 cases of prostatic carcinoma treated by orchiectomy in the University Hospital, and the data published in *THE JOURNAL* (Dec. 5, 1942). The present report is concerned with a subsequent follow-up study made on the same series of cases, and twenty-one months or more have now elapsed in each case since operation. The advantage of following a closed series of cases until the death of the last survivor is obvious; and although this series is numerically a relatively small one, we believe that any obvious trends that are observed in its study might be of value in treating future cases.

All the patients in this series except 4 had infiltrating carcinoma. Forty-three were suffering from pain, cachexia or other clinical manifestations of advanced cancer, and the remaining 32 all had obvious primary lesions but were not suffering subjective disturbance from metastases even though some of them were shown by x-ray examination or by phosphatase determination have bony involvement.

CLINICAL RESPONSE TO ORCHIECTOMY

Pain.—The most spectacular feature of these cases is the early and satisfactory relief of pain, which occurs in from twenty to seventy-two hours in most instances in which relief is obtained. We have observed 2 or 3 exceptions to this general rule, however, in cases in which relief of pain came on very gradually after a period of several weeks. Forty-two of the patients complained of pain on admission. Five of the patients obtained no relief whatever following operation, while 27 have obtained complete relief of pain and 10 obtained partial relief.

Weight.—Eighteen patients complained of significant weight loss on admission to the hospital. Thirteen of these regained their weight losses; however, 38 additional patients had appreciable gains in weight following orchiectomy, some gaining as much as 50 to 60 pounds (about 25 Kg.). There are doubtless many factors which contribute to these postcastration increases in weight.

Urinary Obstruction.—Fourteen patients complained of difficulty with voiding or complete retention of urine on whom orchiectomy was performed and on whom no operation for the relief of prostatic obstruction was carried out. Five of these patients were placed on suprapubic drainage at the time of orchiectomy and all of them were eventually able to urinate satisfactorily so that the cystotomy tubes were removed. Nine patients at the time of orchiectomy complained of significant difficulty with urination, and all have experienced more normal urination subsequent to castration.

Transverse Myelitis.—Two patients were admitted to the hospital complaining of severe metastatic pain and

complete transverse myelitis below the mid-dorsal level. Both had complete relief of pain and complete return of neuromuscular function following orchiectomy, and both patients have subsequently had a recurrence of symptoms and have died.

SUMMARY OF RESULTS

Ten of the patients in this series derived no benefit whatever from orchiectomy; 5 died within six months of operation while 4 died during the ensuing fifteen months and 1 is still alive twenty-two months after castration.

Sixty-five of the patients were improved clinically by orchiectomy, but many of these have derived only temporary benefit. Duration of clinical improvement in the delayed failure group has been variable and we have found no criteria for predicting the prognosis in any case. Comparison of data compiled fifteen months ago and now is as follows:

At the time of the first report there were 20 failures, including 5 dead, and since that time 21 additional patients have had a recurrence of symptoms. One third of the patients have now died of their primary disease, 20 having died during the past fifteen months.

At the present time 34 of the patients continue to enjoy a favorable response to orchiectomy. These are all free from pain and cachexia or other subjective manifestations of extensive carcinoma, and in most

instances the objective signs of their disease—size of the primary tumor, hardness of the prostate gland, x-ray evidence of metastases, serum phosphatase levels—have remained at a measurably improved level since operation. However, all of the favorable response cases, with 4 exceptions, continue to show unmistakable clinical signs of prostatic cancer, a fact which affords additional evidence to suggest that orchiectomy provides only temporary suppression of neoplastic activity. Since the control of prostatic cancer activity by hormonal modifications as now practiced is only temporary and since consequently the resulting clinical improvement is palliative and not curative, one might logically raise the question as to the most favorable time for instituting this form of therapy: Should castration be performed in all cases as soon as the diagnosis of prostatic cancer is established, or should it be delayed until the clinical manifestations of advanced malignancy have developed? In answering this question the following facts should be borne in mind: Prostatic carcinoma is notoriously variable in its rate of growth and spread and many patients having bony metastases survive comfortably for years without any treatment whatever. Undoubtedly endocrine therapy suppresses the neoplastic development of both early and advanced cases and in each instance it produces a corresponding prolongation of life but it does not permanently retard the growth of the primary tumor nor does it prevent the occurrence or the eventual progression of metastases. Likewise castration in early cases does not preclude the eventual development of terminal pain and cachexia. It therefore would appear rational to delay the insti-

From the Department of Surgery, University of Michigan Medical School.

1. Six cases are here included in which pain was evidenced from local neoplastic extension, but these cases are not included in the group of 43 cases of advanced neoplasm herein reported.

tution of endocrine therapy until pain or cachexia develops, for only by this means can the patient hope to derive the dual benefits of this treatment, viz. prolongation of life by suppression of carcinogenic activity and relief of pain. The employment of this therapeutic agency at a time prior to the onset of symptoms would appear to be premature, for then it might deprive the patient of significant clinical benefits. So it seems apparent that accurate timing is required for the most economical expenditure of hormonal control.

The present series of 75 cases has been broken down into two groups for the purpose of comparative study. Those in which there were no symptoms of advanced disease at the time of castration comprise group 1, while those in which pain, cachexia or other complaints were present make up group 2. They are summarized in the table.

In group 1 the high survival rate is not unexpected or surprising. Bumpus studied 1,000 cases of prostatic cancer at the Mayo Clinic in 1926 and found that the average survival period of the entire group was thirty-one months after diagnosis. The incidence at this time of 31.3 per cent of failure cases in group 1 clearly demonstrates that castration does not constitute prophylaxis against the occurrence or development of metastases.

Additional data compiled on group 2 are of particular interest in evaluating this method of treatment. The 12 patients who are living and well have all survived twenty-one months or more, the longest period since operation being thirty-six months. The 10 failures in this group who are still alive enjoyed a favorable response for an average of 11.4 months. The terminal stage in delayed failure cases has been of short duration in most instances.

The average duration of life in the group of 21 who died was 11.3 months, although 7 of these survived less than nine months. The latter figures gain added significance when compared with those compiled by Bumpus, who found that when metastases had occurred at the time of examination two thirds of the patients died within nine months. An advantage of endocrine therapy is indicated by the fact that only 7 of our patients (16 per cent) having metastases which were producing pain at the time of orchiectomy failed to survive the nine months period. The survival of 84 per cent as compared to 33 per cent in the Bumpus series, at the stated interval of time, is obviously to be credited to advance in our methods of treatment.

In this series there has been no effort made to compare the efficiency of estrogenic therapy with that of castration. The relative worth of the two methods can be appraised only by a study of controlled parallel series. We are at the present time treating a series of patients with diethylstilbestrol² and will report the results observed in that group at a later date.

In the present series there were 2 patients who obtained relief of pain following castration who had previously failed to derive any benefit from the ingestion of diethylstilbestrol 3 mg. daily for several weeks. Likewise there are now 2 of the orchiectomy delayed failure patients who were relieved of their recurrent pain following administration of the estrogenic substance.

CONCLUSIONS

A second follow-up study conducted on a series of patients treated by orchiectomy for prostatic cancer gives continued evidence of the value of this form of treatment.

Forty-five per cent of the patients remain free from symptoms twenty-one to thirty-six months after orchiectomy, but 21 patients previously reported as showing favorable response have had recurrent symptoms of advanced disease and several of these are dead. The increasing incidence of delayed failure in this series suggests that eventually all cases may fall into this category.

It is evident that endocrine therapy increases the life expectancy of patients with prostatic cancer by causing a suppression of carcinogenic activity for temporary but varying periods of time; and this temporary control of the neoplasm is accompanied clinically by a period of relief from symptoms resulting from the malignant disease.

It would seem logical to conclude that the maximum benefit to the patient may be derived by delaying endocrine treatment until indicated by the onset of symptoms arising from advanced or metastatic lesions. Only in this manner can the longest period of palliative relief be assured.

THE CONSERVATIVE TREATMENT OF CHRONIC BURSITIS

BY INJECTION OF SCLEROTIC AGENTS COMBINED WITH DRAINAGE

JOHN C. COTTRELL, M.D., M.Sc. (MED.)
LONG BEACH, CALIF.

Chronic bursitis has long been successfully treated by injection of a chemical sclerotic agent into the endothelial sac, effecting an obliteration of the sac by adhesive fusion of its surfaces.¹ An accepted practice consists in aspiration of the sac, introduction of an irritant, withdrawal of some part of the irritant and the application of a compressive dressing. Reeffusion, if any thereafter, is aspirated as required. In the main, this method has given satisfaction.²

To reduce the number of respirations ordinarily necessary after the usual method of care, a variation in technic has been adopted which shortens treatment time and facilitates fusion.

Increase in cases is resulting from the greater number of workmen laboring in confined spaces where elbows and knees come in frequent contact with hard surfaces. Cases here reported were seen in a group of shipyard workmen.³

A variety of pathologic types of bursitis were encountered. Fifty cases of bursitis have been observed, of which 30 were olecranon bursitis, 18 prepatellar bursitis and 2 semimembranosus bursitis (Baker's cyst) in the popliteal space. Of the 30 cases of olecranon bursitis, 3 presented acute hemorrhage in the sac, 8 presented infected sacs and 19 presented chronic effusion. Of the 18 cases of prepatellar bursitis, 4 presented hemorrhage in the sac, 2 infection and 12 chronic effusion. Of the 2 cases of popliteal bursitis, 1 presented hemorrhage and the second chronic effusion.

Appropriate treatment was given patients with hemorrhage and infection. Sacs containing "rice bodies" were surgically excised.

2. Diethylstilbestrol is being supplied by the Eli Lilly Company.

This article deals primarily with chronic bursitis in which effusion has been present for some time, particular consideration being given to the advantage of continuous drainage of the sac after an irritant has been introduced.

Fig. 1.—Specially designed self retaining hollow spooled bursal rubber drain, three times actual size

Initial treatment in all cases of chronic bursitis is administered in the field hospital. This consists of sterile aspiration of the sac followed by the application of a compressive dressing. When it is demonstrated that this simple treatment does not obliterate the sac, chemical obliteration is then undertaken.

Fig. 2—Incision through procaine hydrochloride infiltrated skin over olecranon bursa. Folded rubber bursal drain ready for insertion into bursal sac

The technic employed consists in thorough cleansing the skin, which is painted with an antiseptic. Two per cent procaine hydrochloride is infiltrated intradermally over the sac. A 0.5 cm. transverse incision is then made into the sac, into which is introduced

a specially devised hollow tubed, spool shaped soft rubber drain.⁴ The contents of the sac are allowed to drain off; when empty the sac is refilled through the drain, 2 to 5 cc. of a sclerotic agent being introduced by means of a glass tip syringe inserted in the drain. The sclerotic agent is retained within the sac for five to ten minutes and then drained off. A rubber sponge pad cut out about the drain, which is covered by a fluff dressing, is held in position over the bursal sac by an elastic adhesive dressing which does not encircle the extremity. In some cases the part is further immobilized by an elastic bandage. This primary dressing is left in position twenty-four hours and then a fresh dressing is applied. The drain itself is left in situ forty-eight to ninety-six hours, at the end of which time it is

Fig. 3—Bursal drain in position. Sac distended with sclerotic agent introduced through drain. Agent left in sac five to fifteen minutes, then aspirated off

removed, the compressive dressing being continued. Reexamination after five to seven days usually demonstrates that the sac has been successfully obliterated. In subsequent weeks reeffusion has rarely been observed.

Continuous drainage of an uninfected structure may invite infection. Special consideration was given this potential complication, particularly under circumstances wherein men return to employment in dirty, dust laden environments. In no instance, however, has infection occurred, perhaps because the reactive inflammation set up by the irritant establishes an effective barrier against bacterial invasion.

Materials used for sclerosis were sodium morrhuate 5 and 10 per cent; tincture of iodine 0.5 per cent; proliferol solution and sodium psyllate 5 per cent.⁵ The latter has been found routinely satisfactory, effecting a mild type of irritation without excessive reaction.

Of 15 patients with chronic olecranon bursitis so treated, 14 have been apparently cured. One has a recurrent effusion which will require secondary treat-

ment. The bursae had existed from fourteen days to five months prior to treatment. The period of observation after treatment has extended from one to ten months. The number of office visits required does not range over four or five. Loss of time from work has been minimal.

Eleven cases of prepatellar bursitis were treated with ten apparent cures. One recurrent bursa will require additional attention. Prepatellar bursae so treated have existed from two weeks to twelve months. The period of observation after treatment has ranged from one to eleven months. Again, frequency of visits and time off from work have been minimal.

Chemical obliteration of a popliteal bursa was effective in the case treated. Prior to injection, multiple

Fig. 4.—Drain in position in irritated sac; sponge rubber and gauze compressive dressing applied.

aspirations had adequately demonstrated that the bursa sac did not communicate with the knee joint, which safely permitted this type of treatment.⁶

SUMMARY

Of 50 cases of bursitis of various types involving the olecranon, prepatellar and popliteal bursae, chemical obliteration treatment was used in 27 cases presenting chronic effusion. Other appropriate methods of treatment were used in the remaining cases. In 27 cases treated by chemical obliteration in which a special type of rubber drain was used, 25 have apparently been cured. The number of required office visits is minimal and loss of time from work is short. The use of an indwelling specially devised rubber drain after injection of the irritant appears to reduce the necessity of reaspirations, shortens treatment time and results in a satisfactory number of cures.

ABSORPTION OF INSULIN LABELED WITH RADIOACTIVE IODINE IN HUMAN DIABETES

HOWARD F. ROOT, M.D.

Delay in absorption of insulin from subcutaneous tissues may be one of the factors that reduce the efficiency of insulin and contribute to the condition known as insulin resistance. In 3 diabetic patients with insulin resistance, studies of the respiratory quotient after ingestion of dextrose had indicated so little effect on the quotient even when insulin was given as to suggest that some specific factor might retard the absorption of insulin. When injected intravenously, insulin was more effective than when injected subcutaneously. In 1 of these patients, areas of fatty atrophy under the skin were present not only where insulin had been injected but in certain parts of the body, such as the breasts, where insulin had never been injected. Furthermore, the subcutaneous tissue in certain parts of the thighs and the abdomen of this patient seemed to have a different consistency from the tissue in other parts of the body, so that it appeared likely that the rate of absorption of injected insulin might be different in one part of the abdominal wall from that in another part. In a fourth patient with insulin resistance, the peak of resistance (when 630 units of insulin were required) had passed two years previously, and she exemplified the phase of recovery from resistance. In 3 other diabetic patients the existence of localized fat pads where insulin had been injected too frequently in one spot provided a means of showing whether such changes in tissue affect the rate of insulin absorption. These 7 patients, together with 3 ordinary diabetic patients¹ and 5 nondiabetic controls, afforded an excellent opportunity for measuring the variations in the rates of absorption of insulin after subcutaneous injection by using an insulin labeled with radioactive iodine.

Previous Studies.—The absorption rate of insulin from the site of injection has been previously studied by Beecher and Krogh,² who injected protamine zinc insulin into a rabbit's ear, using methylene blue as a tracer. Biologically active derivatives of crystalline insulin, containing iodine and arsenic, have been prepared by Lang and Reiner.³ Reiner, Keston and Green⁴ studied the absorption and the distribution in animals of an insulin derivative containing radio-

active iodine. Ten rabbits were injected subcutaneously with two thirds of a unit per kilogram. The rabbits were killed at given intervals, and the skin at the site of injection and corresponding parts of the abdominal wall were removed. Blood samples were taken for sugar determination. The tissues were then analyzed, and the amount of iodine remaining at the site of injection was quantitatively determined. They found that in these small animals the rate of removal of insulin from the site of injection was so rapid that by the end of two hours approximately 80 per cent of the insulin had been absorbed. The fall in blood sugar was greatest at a period from one and one-half to two hours after injection, earlier than is usually found in human beings. In rats one hour after intravenous or intracardiac injection the circulating blood contained a considerable fraction of the radioactive material injected. Relatively large quantities of the material were also found in the liver and the kidneys, suggesting concentration of insulin in these organs. These results provided a method by which the rate of absorption of insulin in human subjects could be measured.

Injection of Radioactive Insulin and Counting the Gamma Rays.—With three exceptions (case 7 and 2 controls), the subjects to receive the insulin com-

Chart 1.—Rate of insulin absorption after subcutaneous injection of 25 units of radioactive insulin-4-iodoazobenzene (normal control subjects). pound⁵ came to the laboratory in the morning without breakfast and also had no lunch. The site of injection was carefully marked with mercurochrome, so that the window of the gamma ray counter could be applied directly over it. A dose of 25 units of radioactive insulin-4-iodoazobenzene⁶ was injected with an ordinary hypodermic needle one-half inch in length, inserted at a slight angle so that the deposit of insulin finally occurred at somewhat less than one-half inch below the surface of the skin, exactly in the center of the ring (three fourths of an inch in diameter) on which the window of the counter rested. The injection was made in the subcutaneous tissue overlying the deltoid muscle except in cases 1, 5, 6 and 7. In case 1 the abdominal tissue was always used for injection, and in cases 5, 6 and 7 (in which there were insulin pads at the hip and in the anterior portion of the thighs) the same pad was used as the site of injection. When the injection was made, care was taken to avoid pinching of the tissue. Without any squeezing of the subcutaneous tissue the needle was inserted quickly, allowed

to remain three or four seconds and then quickly withdrawn. In the normal subjects and in most of the diabetic patients no leakage of insulin out through the needle track occurred. However, in certain of the insulin resistant patients leakage of one or two drops did occur, and this leakage was carefully blotted by

Chart 2.—Rate of insulin absorption after subcutaneous injection of 25 units of radioactive insulin-4-iodoazobenzene (ordinary diabetic patients).

means of sterile gauze. The strength of the insulin was such that an injection of 25 units meant injection of 0.5 cc. by volume. After the injection of insulin the counter was applied immediately. Thereafter the patients returned for counts at intervals of twenty minutes, one hour, two, four and eight hours, the time being carefully measured by a stopwatch in each instance according to a prearranged schedule and recorded.

RESULTS

Rate of Insulin Absorption.—In charts 1 to 5 are presented curves showing the trends of the gamma ray rates as observed with recording counting meters for each subject at each period of measurement following the injection of the radioactive insulin compound. In each chart the rates are expressed as percentages of the initial count and plotted against the time expressed in hours. For example, with the control subject McK. (chart 1) at the end of two hours a count equal to

Chart 3.—Rate of insulin absorption after subcutaneous injection of 25 units of radioactive insulin-4-iodoazobenzene (patients with insulin pads). In cases 5, 6 and 7 the insulin pad had been used as the site of injection for days prior to the study.

60 per cent of the initial count was obtained, indicating the presence at the site of injection of 60 per cent of the injected insulin. One surmises that individual differences in subcutaneous tissue may have been present. With some persons the subcutaneous circulation

might tend to bring about a movement of insulin toward the surface. An explanation for some of the variation is that the actual site of injection may not have been in all instances in the center of the circle but, because of the length of the needle, off to one side. Variations in depth of insertion of the needle also will produce slight differences in count because of the absorption in tissue of emerging gamma rays. However, sufficient counts were made in each instance to give a clear picture of the rate of absorption.

The curves obtained with the normal controls (chart 1) and the ordinary diabetic patients (chart 2) are strikingly similar in nature. They indicate that the rate of insulin absorption was rapid during the first one to two hours and became progressively slower during the next four to six hours.

A striking contrast appears in the patients who had insulin pads (chart 3). Large, firm, fatty pads, seemingly fully 1 inch in depth, occurred over the head of each femur of patient 5, where she had long injected insulin because, with the development of the pad, the injections became painless. In cases 6 and 7 the fatty pad had developed similarly because of repeated injections, but for a much shorter period than in case 5. However, these pads had not been used as a site of injection for a number of days prior to our study.

Chart 4.—Rate of insulin absorption after subcutaneous injection of 25 units of radioactive insulin-4-iodoazobenzene (insulin resistant diabetic patients). Case 4 represents a stage in recovery from insulin resistance.

This had resulted in rapid softening of the pads, and they had become much thinner, so that the insulin actually was deposited in more nearly normal tissue under the pad. Case 5 showed an extraordinary delay in insulin absorption, whereas cases 6 and 7 gave normal absorption curves (chart 3). A rapid change in rate of insulin absorption can therefore be brought about by cessation of repeated injections into an insulin pad.

Among the 4 insulin resistant patients the curves for patients 1, 2 and 3 (chart 4) show a definite delay in insulin absorption, especially during the first two hours, and in these 3 instances the delay in absorption persisted even to the eighth hour. In cases 1, 2 and 3 diabetes had existed for 20, 4 and 11 years. The diabetes had been strikingly mild for 18, 2 and 10 years respectively when the condition of insulin resistance developed. The diabetes of patient 4 was of 7.6 years' duration. She had had insulin resistance for more than seven years, but great improvement had occurred in the last two years. The decline in insulin requirement is associated with a curve (chart 4) indicating an almost normal rate of insulin absorption. Patient 1 also has shown such improve-

ment during the ten months since these studies. She has gained weight, and the subcutaneous tissue seems more nearly normal.

The differences in the average rates of absorption of insulin by the three groups control, ordinary diabetic patients and resistive patients are shown in chart 5. When the results are plotted on semilogarithmic graph paper the curves do not become straight lines but retain a curvature somewhat similar to their appearance in charts 1 to 5. This means that the rate of uptake of insulin from the site of injection does not correspond to a constant fractional absorption having a single absorption coefficient. The absolute rate and the fractional rate of absorption are both most rapid immediately after injection, and both decline steadily as the most accessible insulin is absorbed from the tissues of the injection site.

Blood Sugar.—Periodically throughout the day of the test (Nov. 29, 1942) blood sugar determinations (table 1) were made with capillary blood to show the effect of injections of insulin on blood sugar and to ascertain whether wide variations in the level of blood sugar might of themselves affect the rate of withdrawal of the injected insulin from the subcutaneous tissue. Actually it was not justifiable to give each patient 25 units of the radioactive insulin only, because the

insulin resistant patients were accustomed to receiving large amounts of insulin in the morning, and unless in such cases the 25 units of radioactive insulin had been supplemented by other insulin the blood sugar might have risen to an excessive level. Furthermore, since the diabetic patients with 1 exception received no break-

Chart 5.—Comparison of the average rates of insulin absorption of normal controls, ordinary diabetic patients and insulin resistant diabetic patients

fast, 100 cc. of orange juice was given each hour to avoid hypoglycemia. The five normal controls, of whom 2 had taken a light breakfast, received no food during the test. Four showed a decline in blood sugar consistent with the insulin dose of 25 units. And was an exception. In one control subject, Vol, hunger and sweating developed at the end of four hours, suggesting hypoglycemia. He therefore took food, with the result that the blood sugar at the end of four hours rose from 70 to 123 mg. In the 4 resistant cases, supplementary doses of one-half the usual morning doses of insulin were given, the amounts varying between 50 and 100 units. In these 4 cases (cases 1 to 4) the blood sugar values rose during the first two hours and failed to reach normal levels at six hours. The other 6 diabetic patients actually showed a decline in blood sugar during the four to six hours such that hypoglycemic reactions occurred, requiring still further additional carbohydrate in the form of orange juice. The 25 units of radioactive insulin was therefore fully as effective in reducing the blood sugar as had been anticipated. The insulin resistant cases stand out in distinct contrast to all the other cases.

If patients 5 and 6 are compared (patient 7 had taken breakfast), it is seen that insulin pads affect the blood sugar curves. Patient 5 usually received 10 units of crystalline and 30 units of protamine zinc insulin; patient 6, 13 and 44 units, respec-

tively. The 25 units of radioactive insulin was therefore a relatively larger dose for patient 5 than for patient 6, especially in view of the omission of breakfast and lunch. At the end of one hour the blood sugar of patient 5 had fallen only 23 mg., but that of patient 6 had fallen 143 mg. The rates of decline were almost the same in the second hour, but in the fourth and sixth hours patient 5 showed a decline to a hypoglycemic level. The maximum fall in blood sugar was 183 mg. for patient 5 and 190 mg. for patient 6. When the difference in weight of these patients (patient 5 weighed 96 pounds, or 43.5 Kg., and patient 6 112 pounds, or 51 Kg.) and therefore the difference in the total dextrose content of the body fluids are considered, it is evident that insulin probably caused oxidation or storage of a much larger quantity of dextrose in patient 6 than in patient 5.

Patients 8, 9 and 10 were young persons with uncomplicated diabetes under good dietary control. Under such conditions the 25 units of insulin, with orange juice each hour, prevented wide variations in blood sugar, although each patient complained of hypoglycemic symptoms in the third to fifth hours and received extra orange juice. The average maximum fall in blood sugar at four hours was 19 mg. for the normal controls (without breakfast) and 44 mg. for these 3 diabetic patients, an evidence of the ability of the nondiabetic organism to withstand the effect of added insulin. Although the rate of insulin absorption was approximately the same, the fall in blood sugar and the development of hypoglycemic symptoms in the diabetic patients, in spite of their receiving orange juice each hour, showed a susceptibility to hypoglycemia not exhibited by the normal subjects, of whom only Vol received food after the injection.

The hypothesis that hyperglycemia might accelerate and hypoglycemia delay insulin absorption from the site of injection is not supported by the data. It is likely, therefore, that local tissue conditions affect the rate of withdrawal of injected insulin rather than the level of the blood sugar. As the level of the blood sugar must be regarded as correlated not only with the level of sugar in the intercellular fluid but also with the dextrose concentration and the dextrose metabolism in the cells, it is also probable that the rate of insulin absorption is not conditioned solely by the state of intracellular dextrose metabolism.

Measurement of Radioactive Substance in Twenty-Four Hour Urinary Excretion.—Although no methods were available by which we could quantitate the excretion of insulin into the urine, it was felt desirable that a measurement should be made of the radioactive substance found in the urine excreted during the twenty-four hours following the injection. In all probability the amount of radioactive substance found in the urine represented the amount of iodine present in some organic combination. It is impossible to conclude, however, that the iodine excreted in the urine was still in combination with insulin, and therefore it is impossible to infer anything with regard to the excretion of the insulin injected. The results of the measurements are shown in table 2, in which the amount of radioactive substance found in the urine is expressed as a percentage of the total radioactive substance injected. In general, the lower values for the excretion of radioactive iodine are found in the 4 resistant patients, although patient 2 excreted 74 per cent. Among the patients with pads, the one who had the greatest delay in absorption, patient 5, excreted 66 per cent.

FACTORS INFLUENCING INSULIN ABSORPTION

The molecule of the insulin compound employed is somewhat larger than the unimixed insulin molecule. Possibly this larger molecule would be less rapidly absorbed than ordinary insulin. Furthermore, the ratio of the insulin dose to body weight is significant.

Although Reiner, Keston and Green⁴ gave their rabbits two thirds of a unit per kilogram, in our study the insulin dose of 25 units amounted to between one third and one half of a unit per kilogram. It is also true that insulin is less rapidly absorbed in human subjects than in small animals. Reiner, Lang, Irvine, Peacock and Evans⁶ have shown with rabbits that only 22 per cent of injected crystalline insulin remained at the end of five hours. Globin zinc insulin was more slowly absorbed, but protamine zinc insulin was most gradually removed, so that 60 per cent of the protamine zinc insulin remained at the site of injection at the end of ten hours. Regardless of the differences between animals and human subjects, however, the object of our study was to use a constant dose of the compound in a group of patients and a group of normal controls to determine whether there were significant differences in the rates of absorption among the different individuals.

The normal controls and the ordinary diabetic patients showed an almost equal rate of insulin absorption, and their curves are well within the range of physiologic variation. The patients with insulin resistance and insulin pads showed interesting differences. Slow absorption of insulin from the site of injection occurred in 3 patients with insulin resistance and in 1 patient whose insulin dose was injected certainly into the middle of an insulin pad. Patient 4, formerly

requiring 630 units, had so improved that she took only 120 units a day. This fact seems to correlate well with her nearly normal curve. Insulin injected into an insulin pad may be slowly liberated. This may explain the well known clinical observation that patients who use such insulin pads do lose in the efficiency of insulin and may require a correspondingly higher dose.

The cases with insulin resistance require more detailed consideration. An abnormal metabolic rate might be supposed to influence absorption of injected insulin. In the 4 cases of insulin resistance the basal metabolic rate had been found to be within normal limits on a number of occasions (see appendix). Certainly in none was there any suggestion of a lower basal metabolic rate which could influence the rate of absorption. The general circulation, as indicated by cardiac size, blood pressure and the absence of edema, gave no explanation for the delay in absorption. It might be supposed that in these persons some peculiar sensitiveness to injected insulin could produce local thrombosis of vessels, with impairment in absorption. If this was the case, no evidence in the form of localized swelling or redness was apparent.

The state of allergy to insulin is well known to be associated with insulin resistance. At the New England Deaconess Hospital⁷ a small number of patients have been observed who developed simultaneously a high degree of insulin resistance and an allergic state characterized by the appearance of general urticaria, when insulin was given. This condition has always occurred in patients who have previously taken insulin but then have stopped it for some months. On resumption of the use of insulin, the state of allergy to insulin was apparent. In certain cases, study of the blood serum has shown the presence of a large amount of specific insulin antibodies. In case 1, urticaria had at one time followed insulin injection. The blood serum of patient 4 did show specific insulin antibodies in large amount, and a persistent eosinophilia usually exceeding 20 per cent occurred. At this time (in 1936) she required 630 units daily. In 2 of 4 insulin resistant patients, therefore, either urticarial or other allergic manifestations had been present in the past. The dura-

tion of insulin treatment prior to the development of insulin resistance was usually less than two years. Persistence in the use of large doses of insulin has always resulted in a reduction in the insulin requirement, and, as illustrated by case 4, seems to be paralleled by an improvement in the rate of absorption of injected insulin.

6 Complete details for the preparation of this compound have already been published (Reiner, Laszlo, Lang, E. H. Irvine, I. W. Jr., Peacock, W., and Evans, R. D. The Absorption Rates of Insulin, Globin Insulin and Protamine Zinc Insulin Labeled with Radioactive Iodine, *J. Pharmacol. & Exper. Therap.* 78: 352-357 (Aug.) 1943). Two additional refinements were introduced for this preparation. Before the protamine was diazotized, it was acidified and treated with a small amount of dilute sodium nitrite solution. The liberated iodine was then extracted with chloroform. After coupling and purifying were carried out as described in the paper mentioned, the insulin 4 iodoazobenzene solution was filtered through a small Berkefeld filter into a sterile vial, which was then closed with a sterile rubber cap. Analysis of the product showed that 10 per cent of the radioactive iodine was coupled with the insulin. This corresponds to 0.13 microgram of iodine per unit or 0.85 atom per molecule of insulin.

CHANGES IN DIABETIC TISSUES ASSOCIATED
WITH INSULIN ADMINISTRATION

The subcutaneous structural changes following repeated injections of insulin previously studied have included areas of inflammation, lipomatosis, increased fibrosis and areas of fatty atrophy. The first report on such structural changes, by Depisch⁸ in 1926, has been followed by numerous careful studies. In 20 per cent of the patients with atrophies studied by Marble and Smith,⁹ areas of induration were likewise found. Areas of lipomatosis have been described by Rowe and Garrison.¹⁰ It is probably true, however, that many of the tumefactions consist of masses of fibrous tissue in response to the repeated trauma of insulin injections. The finding of low grade inflammatory reactions is discussed by Marble and Smith, and reference to the literature on this subject may be found in their article. Areas of fatty atrophy, shown as depressions, particularly in the thighs or in the subcutaneous tissues of the arms where insulin has been given, are common occurrences. In certain instances areas of atrophy have occurred in regions where no insulin has been given, notably in the breasts, as in case 1 of this series. In the study of such patients reported from the New England Deaconess Hospital by Marble and Smith,⁹ tissues excised from areas of atrophy in 4 patients were subjected to microscopic examination and, in addition, analyses were made of the subcutaneous fat in diabetic and normal rats. In both the rats and the patients the striking change noted was the loss of fat, chiefly neutral fat. The histologic study bore out the impression that the process consisted in the simple disappearance of stored fat, as by lipolysis, without evidence of an inflammatory reaction.

The presence in human subcutaneous fat of a lipase that may split tributyrin and, to a lesser extent, triolein has been demonstrated, and the effect of insulin on this lipase under various conditions is being studied by Marble and Smith. The conjecture has been made, but never confirmed, that in the immediate neighborhood of injected insulin a highly increased rate of dextrose combustion takes place and that an increased destruction of fat follows. Actually, in general, the patients who develop fatty atrophy when using insulin are often those who take small doses of insulin, and there is no general tendency toward the development of insulin resistance in patients who show fatty atrophy.

Fatty atrophy in the subcutaneous tissues, therefore, does not afford a profitable comparison to explain the change in rate of insulin absorption observed in the patients of our series, although the supposition may reasonably be entertained that in some of our cases the long continued injections of insulin might have provoked some disappearance of fat and relative increase in the fibrous stroma in the subcutaneous tissues resembling that seen in areas of insulin atrophy.

Patients with insulin resistance frequently have gone through periods of relatively mild diabetes varying in length from months to twenty years, and then in a

few months (see case 1 in appendix) they have developed insulin resistance. The clinical importance of insulin resistance is that it may develop rapidly in patients whose diabetes has long been mild and the insulin dose only moderate. The physician may fail to recognize the necessity for massive doses of insulin. The patient's death in coma may be erroneously ascribed to insulin failure, when actually the cause was the administration of insufficient insulin.

The changes in local tissue associated with the formation of the insulin pad can disappear rapidly. In cases 6 and 7, in which the insulin pads were rapidly disappearing, the rate of insulin absorption was actually a little better than that of the nondiabetic normal subjects. This raises the question whether the rate of absorption of insulin may be influenced by the need of the tissues for insulin. It is conceivable that in the patient with moderately severe diabetes a condition of "insulin hunger" exists, in contrast to the condition of the nondiabetic subject who has a normal supply of insulin from his own pancreas. Therefore the rate of absorption of injected insulin might well be slower in normal than in diabetic tissue. Possibly this explains the fact that in the ordinary diabetic patients and in the 2 patients who were recovering from the formation of insulin pads the rate of absorption of insulin was apparently equal to or even a little better than that of the nondiabetic controls, particularly if the values at the six hour period are compared. The average amount of radioactivity remaining at the end of six hours was 48 per cent in the 5 normal controls, whereas it was only 36 per cent in the 2 patients recovering from the formation of insulin pads. On the day of the test the insulin was injected into these 2 persons through areas of pad formation that had previously been deliberately avoided for ten days or more in the administration of insulin. Therefore, not only had the pad rapidly subsided in these patients but there had been no local trauma or irritation from insulin for a long period. It is common knowledge that diabetic patients who systematically practice giving insulin injections according to a map may avoid injecting insulin into the same area for ten days or even a month. Such patients rarely have any local evidences of trauma from insulin, and it is usually thought that they get better absorption of insulin. These data afford clear proof of the importance of planning insulin injections on a definite schedule, so that the same site of injection will not be used more than once in two weeks.

Extraordinary differences in the rate of absorption of injected insulin can be demonstrated in different diabetic patients. We cannot conclude that the phenomenon of insulin resistance is entirely explained by these variations in local tissue absorption. Other recognized causes for insulin resistance include (1) hyperactivity of the insulin antagonists, namely the pituitary and the adrenals, (2) disturbances in liver function, (3) infection, (4) excessive destruction of the insulin producing apparatus, as in carcinoma of the pancreas, (5) allergic states, particularly with widespread disturbance in the carbohydrate storage of the skin and the production of specific insulin antibodies, (6) hypermetabolism associated with hyperthyroidism, and (7) acidosis. Nevertheless, in patients who have insulin resistance requiring large doses of insulin, remarkable changes in the rate of absorption of insulin do some-

times occur. The cause seems to be some metabolic or structural change in the tissues that receive the injections, but this change may also be present in other tissues such as the liver or muscles, to which insulin is conveyed by the blood. This investigation suggests

the practicability of using some radioactive substance with human subjects in studying the absorption of other drugs injected subcutaneously, about which little is known at the present time.

SUMMARY

1. The rate of absorption of 25 units of insulin-4-iodoazobenzene (one-third to one-half unit per kilogram) labeled with radioactive iodine and injected subcutaneously was measured for eight hours in 10 diabetic patients and 5 normal controls.

2. In the normal controls and the patients with uncomplicated diabetes, insulin absorption took place at an almost equal rate, which was rapid during the first two hours but became progressively slower.

3. Areas of induration or of pad formation caused pronounced retardation of insulin absorption. Yet, when such insulin pads had rapidly disappeared because of cessation of injection in the area, the tissues regained the power of rapid absorption of insulin.

4. Patients with idiopathic insulin resistance showed significant delay in insulin absorption. In such cases insulin produced a more definite effect on blood sugar and respiratory quotient when injected intravenously than when injected subcutaneously. During recovery from insulin resistance, the rate of absorption became normal.

5. In the normal controls and in all the diabetic patients except those with insulin resistance, the blood sugar declined after insulin injection. In the resistant patients, the blood sugar rose during the first two hours and had not reached normal levels at the sixth hour. Wide variations in the initial level of blood sugar did not of themselves affect the rate of insulin absorption.

6. The cause of delayed insulin absorption is not related to long duration of diabetes but is resident in the tissues at the site of injection and tends to be corrected by the continued use of insulin in amounts large enough to control glycosuria and hyperglycemia.

7. A comparison of the rates of insulin absorption from the standpoint of differences in the structure of

the tissues used for injection, with particular reference to the disappearance of insulin pads and of areas of fatty atrophy, suggests the hypothesis that in cases of insulin resistance which is associated with pronounced delay in insulin absorption, the metabolic or structural changes in diabetic tissues take place under the influence of some factor such as a disturbance in hormonal and enzyme relationships.

APPENDIX

In table 3 are summarized the clinical data, including the usual diets and insulin dosage, of the 10 diabetic patients used in our study. They are classified under four headings: (1) insulin resistant patients (1 to 4), (2) a patient (5) with thick insulin pads 3 to 4 inches in diameter and fully 1 inch in depth, apparently fatty or fibrous in structure, (3) 2 patients (6 and 7) with areas of thin insulin pads typical of recovery from the effect of repeated insulin injection at the same site, and (4) 3 diabetic patients (8 to 10) of ordinary type without evidence of insulin resistance or changes in the subcutaneous tissue.

With all 4 of the insulin resistant patients, detailed metabolic studies were made, including measurements of the respiratory quotient and the gaseous exchange both under basal, postabsorptive conditions and after the administration of dextrose with and without ordinary crystalline insulin. In 3, insulin given subcutaneously had slight effect on the metabolism unless given in massive doses. Patient 4 showed that partial recovery from insulin resistance had occurred, and improvement in the response to insulin was found.

The contrast between the effects of insulin given subcutaneously and by vein is shown for patient 1 in table 4. With this patient, after 400 units of insulin given subcutaneously and 50 Gm. of dextrose by mouth, no appreciable rise in the respiratory quotient was observed. However, after 200 units of insulin intravenously and 50 Gm. of dextrose by mouth, a slight

but significant rise in the quotient was observed. In all probability variations in structure occurred in different portions of the tissues used for insulin injection. On palpation, the subcutaneous tissue of this patient's abdomen felt distinctly inelastic, thickened, firm and rather fibrous. The same was true in certain portions of the thighs. Nevertheless there were certain areas where the tissue felt much more nearly normal. Indeed, on one occasion, when 300 units of insulin was given subcutaneously in another area and 50 Gm. of dextrose by mouth, a rise in respiratory quotient was obtained.

Clinical and x-ray studies of the pituitary of this patient were negative. Dr. Francis Lowell found in her blood some anti-insulin substances in low concentration. An attempt to use human insulin, on the basis that her resistance to insulin might be due to

a species effect, was unsuccessful. Her diabetes had been mild for eighteen years, when insulin treatment was begun in February 1940. Then she required only 30 units daily. The phase of insulin resistance appeared in November 1941. Her insulin requirement gradually increased until in the period from December 1941 to August 1942 she took from 1,400 to 2,100 units daily. The dose had been reduced during the intervening weeks to 650 units daily.

In case 2 the effects of 50 Gm. of dextrose given intravenously on two different occasions are compared, first, when 100 units of crystalline insulin was given subcutaneously and, second, when 150 units was given intravenously. Only a slight rise in respiratory quotient (table 5) and no decline in blood sugar followed the subcutaneous injection, whereas with the intravenous injection a rapid rise in respiratory quotient and a fall in blood sugar occurred. The difference in results is too great to be explained by the difference in insulin dosage.

CESAREAN SECTION UNDER CONTINUOUS CAUDAL ANALGESIA

A PRELIMINARY REPORT

CLIFFORD B. LULL, M.D.

AND

JOHN C. ULLERY, M.D.

PHILADELPHIA

We recognize and accept the fact that the introduction of any new drug or method of treatment is usually followed by repercussions from many sources. This is particularly true if the public is informed prematurely. Unfortunately, this has happened with the introduction of continuous caudal analgesia by Drs. Hingson and Edwards¹ of the United States Public Health Service. It is not our purpose to discuss the history, use or dangers of caudal block or to compare the various methods of technic, but to endorse this new procedure as the nearest thing to safe and painless childbirth that we have in our obstetric armamentarium. After reading a report of 10,000 cases of childbirth compiled by Hingson and Edwards, and from our personal observation in 950 deliveries by this technic, we agree with the originators of this method and with other writers that it is a procedure which should be used only in a well staffed obstetric service by competent specially trained individuals. We feel sure that continuous caudal analgesia will have a definite place among the analgesic agents used in obstetric practice.

The staff of the Philadelphia Lying-in Hospital considers it a distinct pleasure to have been of assistance to Hingson and Edwards in the development of this method. We attribute the high percentage of our successful cases to the fact that the originators have been with us during most of the trial period and we have had the benefit of their advice in handling these patients.

Realizing that any new procedure has to be tried slowly and carefully, we have endeavored to surround our patients with every possible safeguard, and now after a year's experience without any maternal or fetal death attributed to its use we feel we are in a position to give continuous caudal analgesia our endorsement.

When cesarean section is indicated, three things are of paramount importance: first, the time to do the operation; second, the type of operation to be performed; and, third, the anesthetic agent to be used.

The ill effects of various drugs and inhalation anesthesia on the unborn child have long been recognized. Because of the dangers associated with one dose spinal anesthesia for cesarean section, this method was discontinued in all but a few clinics and for some years a local anesthetic agent has been looked on as the safest for mother and child. Our experience with local anesthesia for cesarean section has been most satisfactory, but not every patient is suitable for this type of anesthesia, and not all surgeons have the necessary tranquillity to use it. The introduction of continuous or fractional spinal anesthesia by Lemmon and the use of smaller doses of less toxic drugs brought about a revival of this type of anesthetic in our section cases and for the past two and a half years we have used a general anesthetic only occasionally. Our results from one dose caudal analgesia were not particularly gratifying.

1. Hingson, Robert A., and Edwards, Waldo B.: Continuous Caudal Analgesia in Obstetrics, J. A. M. A. 121: 225-229 (Jan. 23) 1943.

although Lahmann and Mietus² report satisfactory results in all but 3 of 48 cases. In 2 of the cases the caudal block wore off before the operation was completed and the closure of the abdomen was completed after pentothal sodium was administered intravenously. In another instance analgesia resulted, but the anesthesia on the anterior abdominal wall failed to rise sufficiently high to permit an adequate incision. This patient's block was complemented by nitrous oxide anesthesia. They reported no maternal deaths, and the three fetal deaths could not be attributed to the technic or type of anesthetic. They, as all writers on this subject, call attention to the necessity of having the patient surrounded by safety measures and conclude that caudal anesthesia is well suited for cesarean section. After observing the results of continuous caudal anesthesia in several hundred vaginal deliveries, we extended its use for immediate puerperal sterilization. Our results were satisfactory. Following this we have attempted to evaluate its use for cesarean section and herewith is a report on our observation in 50 cases. Twenty-nine of the patients were operated on at the Philadelphia Lying-in Hospital, 3 at the Jefferson Medical College Hospital and 2 at the Philadelphia General Hospital. We are indebted for the addition of 12 cases managed by Hingson and Edwards at the Marine Hospital, Staten Island, and the report of 4 patients operated on by Dr. John C. Hirst at the Preston Retreat, to be included in this series.

In our series the indications for operation were as shown in table 1.

Mental reassurance should be included in the usual preoperative preparation of a patient who is going to be conscious during a surgical procedure. The type of anesthesia to be used is never discussed until the patient has been hospitalized, when the operation is elective; that is, the decision to perform cesarean section is made prior to the onset of labor because of clearcut indications. If the anesthesia is discussed previous to admission, the patient is sure to discuss it with a friend, who supposedly has heard of a patient whose anesthetic wore off before the operation was completed or who died from the use of a spinal injection. It will take some time to educate the public to the value of continuous spinal and caudal methods of anesthesia, and although we have had no patient who has absolutely refused it, several have been very doubtful about taking it. An interesting point is that each of the patients who protested mildly against its use were most enthusiastic on completion of the operation. For example, one patient who had had a previous cesarean section under gas-ether sequence told us that the day after her second cesarean section, which was under continuous caudal anesthesia, she felt as good as she did on the fifth day after her first operation.

In addition to the mental preparation of the patient it is advisable to prepare the family for the length of time the patient is required to remain in the operating theater. It is essential that the operation not be started until the anesthesia is complete; and, in order that the family may not be unduly worried, it should be acquainted with this necessary delay.

Quiet in the operating room is most important, as the dropping of instruments and pans, or loud talking, disturbs the patient. An indispensable part of the operating team is the anesthetist, who remains at the head of the table and reassures the patient while carrying on a low toned conversation with her at least until the

baby is delivered. All fear usually leaves the patient immediately after she hears the baby cry, and the operation is completed in an entirely different atmosphere.

The contraindications for using continuous caudal analgesia are:

1. Gross deformities of the spine, particularly of the sacrum.
2. Tumors which narrow the spinal canal.
3. Local infection around the sacral hiatus
4. Skin infections such as boils or carbuncles anywhere on the body (a contraindication to be evaluated by the physician in charge).
5. History of sensitivity to the analgesic agent.
6. Profound anemia, unless supplemented with oxygen inhalation.

We have hesitated to use this technic in cases of placenta previa because of the relaxation of the cervix and the possibility of bleeding. This is particularly true if the patient has had any uterine contractions.

In addition, caudal analgesia is seldom satisfactory in hysterical patients, and some women do not like it because their fear of childbirth is such that they dread being conscious during the process.

Severe contractile burn scar of perineum	1
Advanced pulmonary tuberculosis	2

Adequate fluids should be administered preceding the operation, especially in hot weather. One of the barbiturates should be given the previous night and 1½ grains (0.1 Gm.) should be given one hour before operation. Fifty mg. of ephedrine hydrochloride should be given intramuscularly or in the initial solution if the patient's blood pressure is below 140 mm. systolic. In hypertensive cases the ephedrine should be withheld unless the blood pressure falls to 100 mm. systolic.

TECHNIC

The technic of administering the caudal analgesia in cesarean sections is outlined as follows:

1. The patient is given 1½ grains (0.1 Gm.) of a barbiturate one hour before operation, having been given sedation the previous night.

2. One and five-tenths per cent metycaine in 125 cc. of isotonic solution of sodium chloride or isotonic solution of three chlorides is prepared and 50 mg. ephedrine hydrochloride is given intramuscularly at the time of the first injection.

3. The continuous caudal needle is inserted and the apparatus adjusted as for obstetric analgesia.

4. An initial test dose of 8 cc. is administered with careful check by aspiration to prove that the needle is not within the subarachnoid space or a blood vessel.

5. A supplementary dose of 40 to 60 cc., depending on the size of the patient, is then administered. The patient is then placed on her back and the level of analgesia is tested in twenty minutes.

2. Lahmann, Albert H., and Mietus, A. C. Caudal Anesthesia for Cesarean Section, *Am. J. Obst. & Gynec.* 46: 274-278 (Aug.) 1943.

6. If the level of analgesia has not gone above the umbilicus on both sides, a supplementary third injection of 20 to 40 cc., according to the need of the patient, is administered.

7. When the level of analgesia is complete on both sides to the height of the eighth dorsal segment, the operation may be begun. This is usually about thirty minutes after the first injection. In debilitated patients seriously ill with tuberculosis or heart disease, the procedure should be instituted forty-five minutes to one hour before operation and the level of analgesia developed more slowly.

The time required for the analgesic agent to work satisfactorily varies and, if one is to use this method, the operation should never be started before the level of analgesia is correct and repeated injections should not be given with the idea of shortening the length of time before the operation is started. In our series the minimum time before starting the operation was ten minutes, the maximum time one hour twenty minutes and the average time, thirty-four minutes.

In all of our cases but 1 we have used the malleable needle. In the 1 case the ureteral catheter technic was carried out. Since the development of this new malleable needle we have not feared breakage and have had no such accident occur.

There have been several reports of excessive drop in blood pressure when caudal analgesia is used. The average drop in our series, with the exception of 2 patients, was 26 mm. The only patient who had a severe drop of blood pressure was having her second cesarean section. The first cesarean was done four years previously, at which time she had a circulatory collapse at the onset of the operation, which was being done under nitrous oxide-oxygen anesthesia. This patient was an unstable individual with definite glandular imbalance and pronounced instability of her nervous system. She was extremely apprehensive, and because of the circumstances occurring at the time of her first cesarean section we thought that the use of the caudal technic would prevent a recurrence. Identically the same thing happened, however, after we had given only 30 cc. of metycaine, in spite of the fact that she had been given ephedrine. Plasma and other stimulants were ready and were given. The operation was continued in spite of the fact that her blood pressure had not become stabilized. It has been our experience that immediately after the delivery of the child the blood pressure regains its normal level. This has been found to be true in practically every case, and in this instance there was an immediate rise of 60 mm. of pressure within a minute after the child was removed from the uterus. We have not been able to explain this phenomenon to our own satisfaction, but it is an important observation and should be remembered when there is fear of proceeding with the operation because of an unusual drop in blood pressure. None of our cases showed any postoperative blood pressure abnormality.

Recovery of all our patients has been extremely satisfactory, and the amount of postoperative discomfort has been minimal. In no instance was catheterization necessary beyond what is usually necessary following cesarean section. Morbidity occurred in 1 patient who had been in labor with ruptured membranes and who suffered from a mild endometritis after operation. However, her eventual recovery was satisfactory. Morbidity in another was due to pyelitis, which appeared on the seventh postoperative day. No patient complained of backache or unusual pains in the lower

extremities. There were no maternal deaths in our series.

In 48 cases perfect analgesia was obtained. The other 2 included in this series were failures because of inability to insert the needle in 1 case and failure of fusion of the sacrum in the other. These 2 cases demonstrate the fact that it is not possible to give every patient caudal analgesia.

Metycaine was used in all these cases. The minimum amount necessary was 30 cc., the maximum 320 cc., with an average of 81.8 cc.

The minimum duration of the operation was fifteen minutes, the maximum seventy-five minutes and the average, thirty-eight minutes. There is no necessity to hasten the performance of a cesarean section under this procedure because with the needle still in place repeated injections can be given as required. The important thing to remember is to repeat the injection at the slightest evidence of loss of good analgesia.

We do not perform a routine type of cesarean section. The low classic operation has given us very satisfactory results for women who have not been in labor, who have not been examined and whose membranes have not ruptured. The low segment operation is performed when the patient has been in labor, has been examined or has ruptured membranes. If there is any suspicion of potential infection, the Waters modification of the Latsko operation is the procedure of choice. In our series types of operation performed are given in table 2.

TABLE 2.—Types of Operation

Low classic and sterilization.....	11
Low classic.....	27
Low segment operation.....	7
Low classic, myomectomy.....	1
Low classic, salpingectomy.....	1
Waters modification of Latsko.....	8

The extraction of the child is accomplished without pain, but care should be taken not to manipulate the uterus before the incision is made. In 1 of our cases in which the uterus was in dextrorotation and necessitated replacement before incision of the anterior wall the uterus contracted so vigorously that difficulty was experienced with extraction of the child. All babies cried lustily immediately after delivery and none needed resuscitation. All babies except 1 were discharged from the hospital in good condition. One baby was delivered of a seriously toxic mother at five and one-half months and succumbed within eight hours after birth. We do not consider this fetal death attributable to the analgesic agent. Had any other analgesia been used the child probably would not have breathed at all.

The average estimated blood loss in all these cases was 100 cc. In both vaginal and abdominal deliveries under caudal analgesia we have been impressed by the definite decrease in loss of blood. For several years we have been giving one of the ergot or posterior pituitary preparations intravenously in all cesarean sections immediately after extraction of the child. This routine was carried out in the first few of these cases under caudal analgesia but was discontinued when it was found to be unnecessary. However, we do give these preparations intramuscularly as a routine procedure.

The patients are greatly benefited by the administration of morphine and scopolamine immediately after abdominal section or vaginal delivery. This medication relieves the discomfort associated with episiotomy when the analgesic effect has been exhausted.

COMMENT

For some time we have been endeavoring to evaluate various anesthetic and analgesic methods, particularly in cesarean section. Although a definite conclusion cannot be reached after studying a series of only 50 cases, we feel from our observation of this method that it is superior to any other that we have tried. Because of the excellent results in both vaginal delivery and cesarean section, we believe that this method of relieving pain is perfectly safe when given by a trained person in a well equipped maternity department. We have been particularly impressed by the absence of nausea, the complete relaxation of the abdominal wall, the smooth convalescence of the mother with the absence of discomfort after operation and the fact that no baby in this series required resuscitation.

The enthusiasm with which those patients who have had previous sections under inhalation anesthesia accept this new method is very gratifying to us, and the family's reaction is quite different when the patient is returned to her room in a cheerful, wide awake condition.

Although the average person takes this type of analgesia well, it is especially beneficial in cardiac cases, toxemias and upper respiratory infections.

We would like to call attention to the following observations: First, should there be a drop of blood pressure, it returns to normal immediately after delivery of the child; second, perfect analgesia must be obtained before the operation is started; third, the level of analgesia must be maintained throughout the entire procedure.

Our results have been so satisfactory that we feel justified in continuing the use of continuous caudal analgesia until a larger series has been observed.³

SUMMARY

Of 50 patients operated on under continuous caudal analgesia, 48 had perfect results and 2 were failures because of inability to introduce the analgesic agent.

All mothers recovered. There were 2 cases of morbidity not attributable to the use of this method.

Forty-nine babies were discharged from the hospital. One baby born at five and one-half months' gestation died.

Two patients had a drop of blood pressure beyond the average of 26 millimeters.

807 Spruce Street.

3. Since this article was written, our series has increased to 67 cases. Results in the last 17 cases were as satisfactory as in the preceding 50.

Clinical Observations on Itching.—It is obvious from experiments performed early in this century that itching is somehow related to cutaneous pain. In pathological cases of sensory dissociation, in local anesthesia and in asphyxial nerve block the perception of itching disappears and reappears with the pain perception. Complete analgesia is always connected with loss of itching sensitivity, and in cases of complete tactile anesthesia with unimpaired pain sense the itching sensitivity is unimpaired too. Also it has been shown that itching is independent of the temperature senses. Special points in the skin surface responding with itching alone to any stimulus could not be detected, but it was found that pain and itching points have the same density and that they cover each other. The interpretation of all these results was that itching is mediated by pain receptors and pain fibers.—Rothman, Stephen: *The Nature of Itching*, Research Publications, Association for Research in Nervous and Mental Disease, Baltimore, Williams & Wilkins Company, 1943.

Clinical Notes, Suggestions and New Instruments

IDENTIFICATION OF INFLUENZA VIRUS TYPE A IN CURRENT OUTBREAK OF RESPIRATORY DISEASE

JONAS E. SALK, M.D.; WILBUR J. MENKE, M.D., AND
THOMAS FRANCIS JR., M.D., ANN ARBOR, MICH.

Under the direction of the Influenza Commission of the Board for the Investigation and Control of Influenza and other Epidemic Diseases in the United States Army, observation posts have been set up in various parts of the country for early detection of influenza in Army personnel.

In the Virus Laboratory of the University of Michigan School of Public Health, such observations have been carried out for more than a year. On May 28, 1943 in the course of one of many routine surveys, several patients ill with influenza were seen at the Station Hospital, Fort Custer, Michigan. A strain of influenza virus, type A (Weiss), was isolated from the throat washings of 1 of these men, and in 2 other cases positive serologic evidence of type A infection was obtained. Since no epidemic prevalence of influenza or other respiratory disease was noted at that time and the usual seasonal decline followed, it appeared that type A influenza virus could be the cause of sporadic disease.

From the middle of October 1943 the Army Specialized Training Program Unit at the University of Michigan was under constant detailed observation for respiratory disease. On Nov. 17 and 18, 1943 several cases resembling mild influenza appeared at sick call. On November 18 throat washings from 4 of these were inoculated intranasally into ferrets and mice. In 2 instances the ferrets responded, after an incubation period of forty-eight hours, with sharp febrile reactions and nasal signs resembling those usually seen in infection with influenza A. Material from these ferrets obtained at autopsy on the third day was inoculated into the chorioallantoic sac of chick embryos, some given intranasally to mice and some passed to additional ferrets. Eggs of the first passage of one revealed the presence of red cell agglutination¹ in the allantoic fluid. Type A influenza virus was identified by the agglutinin inhibition reaction. Type A virus was also identified in eggs inoculated intrallantoically with material from the second ferret passage of the other throat washing.

Mice of the third passage of those inoculated with the original throat washings from 1 patient developed pulmonary lesions due to influenza A virus. Influenza A virus was established in mice inoculated with material from the second ferret passage of the throat washings from the second patient. Mice inoculated with throat washings of these 2 patients were immune to the PR8² and Weiss (May 1943) strains of influenza virus type A when tested fourteen days later with 10 to 100 lethal doses intranasally. They were not immune to the Lee strain³ of influenza type B. Ferrets allowed to recover from inoculation developed antibodies to type A virus. Study of the acute and convalescent serums of the patients revealed a sharp rise in antibodies to type A virus but not to type B.

The same procedures carried out with the other 2 specimens from clinically similar cases failed to yield any evidence of the presence of influenza A or B. Studies of antibody titers of acute and convalescent serums from additional cases of influenza-like respiratory disease occurring during the first few days of the outbreak have revealed that a definite proportion of illness was not due to influenza A or B.

The present report serves to detail the detection of influenza virus type A at the onset of an epidemic in a Middle Western post before the disease was known to be present in other parts of the country.

From the Department of Epidemiology and the Virus Laboratory, University of Michigan School of Public Health.

These investigations were aided through the Commission on Influenza, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, Preventive Medicine Division, Office of the Surgeon General, United States Army.

This study was also aided by a grant from the International Health Division of the Rockefeller Foundation.

DANGERS OF METHYL CHLORIDE AS
SUBSTITUTE FOR FREON

A STATEMENT BY THE ASSOCIATION'S COMMITTEE
TO STUDY AIR CONDITIONING

ALVAN L. BARACH, M.D.
NEW YORK

C. P. YAGLOU, M.S.
BOSTON
AND

CAREY P. McCORD, M.D.
Chairman of the Committee
DETROIT

Freon (dichlorodifluoromethane), long used as the refrigerant of choice in some types of air conditioning and refrigeration, has become little available through military requirements. This substance is now largely preempted for use as a disperser for one or more insecticides. This gas is almost wholly free of toxic properties, as a result of which engineers, servicemen, physicians and hygienists have become decreasingly aware of earlier disastrous events associated with more dangerous forms of refrigerants.

The mechanism earlier used with Freon does not lend itself to the ready substitution of any and all other refrigerants without extensive alterations. In fact, about the only other refrigerant that may be used in the same mechanism is methyl chloride (CH_3Cl). Even this refrigerant requires some adaptation, such as solves valve changes and the elimination of aluminum and certain other less common metal parts. In contact with aluminum, methyl chloride forms aluminum trimethyl. Practical requirements are leading to the widespread substitution of methyl chloride for Freon, and many governmental specifications call for the use of methyl chloride for air conditioning and refrigeration purposes.

This gas is both toxic and, under some circumstances, explosive. Its general properties are set forth in *Chemical and Engineering News*.¹ Its toxic properties are well described in the article "Methyl Chloride Poisoning from Domestic Refrigerators" by McNally, Kegel and Pope.² Publications now available imply a relative lack of injurious properties of methyl chloride, and in some the statement appears that the toxic threshold for short periods of exposure begins only at such relatively high concentrations as 750 parts per million. To the contrary there exist unpublished data that apparently prove that at least among animals injury may begin with more dilute concentrations and on the order of 100 or 200 parts per million. For sustained exposures it may develop that concentrations higher than 50 parts per million are undesirable. Heretofore emphasis has been placed on acute poisoning with scant reference to chronic states. It is now believed that repeated exposures at intervals such as one week apart may lead to cumulative damage. Already over the country a few minor disasters have occurred, chiefly connected with explosions.

In a recent engineering publication³ a summary of precautions has been published, chiefly connected with

the processes involved in the change over from Freon to methyl chloride. A few of them there appearing are here shown:

- Methyl chloride is toxic and inflammable.
- Do not use methyl chloride in systems where it will come in contact with aluminum or zinc.
- Test the system for leaks BEFORE charging with methyl chloride.
- Do NOT use a halide torch when testing for leaks AFTER the system has been filled with methyl chloride.
- Increase superheat setting of "Freon"-charged thermal expansion valves to maximum. (New orifice may also be needed to reduce capacity of valve.)
- Install dryer in liquid line.

It is not the purpose of this concise statement to condemn the use of methyl chloride. Instead it is desired merely to indicate that the number of instances of methyl chloride poisoning may increase, and that physicians caring for patients employed about air conditioning or refrigeration enterprises should be alert to the emergencies, acute and chronic states that may be induced by methyl chloride under conditions not always certain to attract the attention of the work of patients themselves.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORT.
HOWARD A. CARTER, Secretary.

SONOTONE AUDIOMETER, MODEL 20,
SERIAL NO. 573, ACCEPTABLE

Manufacturer: The Sonotone Corporation, Elmsford, N. Y.
The Sonotone Audiometer, Model 20, is designed to measure the acuity and range of hearing. In the Council's investigation of the instrument, the audiometer was calibrated to determine whether it complied with the minimum requirements for acceptable audiometers of the Council on Physical Therapy.¹

All measurements were made with a 115 volt alternating current, 60 cycle power supply. The acoustical output of the air conduction receiver was measured on a coupler at the audiometer frequencies 128, 256, 512, 1,024, 2,048, 4,096 and 8,192 cycles only.

The instrument is equipped for testing with air and bone conduction. The frequency of the test tones remains within ± 5 per cent of the designated value under the manufacturer's indicated operating conditions. Dials are marked so that frequencies may be identified readily.

Each indicated attenuator level produces a sound pressure which is within ± 5 decibels of the value referred to normal threshold. The normal threshold is that determined in the National Health Survey Hearing Study. Each attenuator step is 5 ± 1.5 decibels.

Range of intensity (air conduction only): The intensity range of the test tones above the normal threshold is at least that as follows:

Test Tone Cycles per Second	Intensity Range Decibels
128	60
256	80
512	85
1,024	90
2,048	90
4,096	90
8,192	70

The sound pressure amplitude of the harmonics in the output of the air conduction receiver does not exceed 3 per cent of the amplitude of the corresponding fundamental frequency.

The frequency dial is calibrated in the traditional octave scale (128, 256, 512, 1,024, 2,048, 4,096, 8,192) and also in the closely equivalent scale (125, 250, 500, 1,000, 2,000 and so on) for easy

1. Minimum Requirements for Acceptable Audiometers. J. A. M. A. 120:838 (Nov. 14) 1942.

interpolation when exploring by sweep methods. The nature of the electrical circuit is such that the frequency is stable, and no zero adjustment of the frequency dial is required.

The air conduction receiver is of the dynamic type, and both the air and bone receivers are especially designed for audiometric purposes.

A masking circuit and receiver are included with separate controls. The masking spectrum is sufficiently broad to provide effective masking at all the audiometer frequencies.

A signal button on a cord is provided for the person who is being tested. An interrupter that introduces no extraneous identifying sounds permits easy determination of threshold values.

A control on the panel allows the audiometer to be set for bone or for air conduction testing. The instrument is inoperative if the air conduction receiver is plugged in while the instrument is set for bone conduction or vice versa. As the control is changed from one of these test positions to the other, a shifting window selects the correct hearing loss values to be read. Receiver plugs are of different types so that the bone, air and masking receivers can be connected only to the proper terminals.

The Council on Physical Therapy voted to accept the Sonotone Audiometer, Model 20, for inclusion in its list of accepted devices, since the instrument was found to comply with the Council's minimum requirements for acceptable audiometers.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS WATCHED CLOSELY THE TREATMENT OF THE MENINGITIDES. BECAUSE OF THE DIFFERENCES IN OPINION OF THE VALUE OF ANTIMENINGOCOCCIC SERUM AND MENINGOCOCCUS ANTITOXIN, IT WAS DECIDED TO PREPARE A STATUS REPORT. ACCORDINGLY, DR. HOBART A. REIMANN WAS APPROACHED FOR ASSISTANCE IN PREPARING SUCH A REVIEW. LETTERS WERE DIRECTED TO TWELVE PERSONS (NOT INCLUDING DR. REIMANN) IN CIVILIAN PRACTICE AND THE ARMED FORCES TO ASCERTAIN THEIR EXPERIENCE. THE FOLLOWING STATEMENT REPRESENTS THE CONSENSUS, AND ITS PUBLICATION HAS BEEN AUTHORIZED BY THE COUNCIL, WHICH WISHES TO EXPRESS ITS APPRECIATION OF THE EFFORTS OF DR. REIMANN AND THE OTHERS WHO AIDED IN THE SURVEY.

AUSTIN E. SMITH, M.D., Secretary.

STATUS OF ANTIMENINGOCOCCIC SERUM AND MENINGOCOCCUS ANTITOXIN

All authorities are agreed on the value of sulfonamide chemotherapy in the treatment of meningitis and septicemia due to the meningococcus organism. Mortality rates in the hands of some physicians have been less than 5 per cent with chemotherapy, and these workers do not believe that antimeningococcic serum given in addition to chemotherapy is of any value; in fact, some suggest that serum may at times even be harmful and contraindicated. The chief disadvantages of serum are its bulkiness, expense, perishability, the complexities of its administration and the frequency of prolonged convalescence from serum sickness.

Many clinicians feel that at present serum should be used only for (a) patients who are sensitive to sulfonamide compounds and (b) patients in whom the meningococcus is or becomes drug resistant. The former criterion (a) is of course valid, but it is an uncommon occurrence; the latter (b) apparently is rarer. According to one worker there is little evidence to indicate that drug resistant meningococci have been encountered in meningitis. Another reports only 1 case out of 2,000 in which the meningococcus seemed to be resistant to sulfadiazine. Several have suggested that serum, in addition to sulfonamides, might be of value in the rare cases of fulminating infection if no specific antibodies can be demonstrated in the patient's serum, but death often occurs before the diagnosis is made, before the meningococcus is classified, before antibodies can be studied or before serum is obtainable or administered. Perhaps antimeningococcic serum should be retained for use in cases in which sulfonamides cannot be used, but instead of using the serum customarily prepared in horses, refined, monovalent concentrated rabbit serum is preferable. In experimental

studies, rabbit serum was found to be ten times as potent as horse serum and is far more easily prepared.

Meningococcic Antitoxic Serum.—As regards Meningococcic Antitoxic Serum, several authorities do not recommend its use. Others feel that there is no evidence that an exotoxin is made by the meningococcus but that endotoxins may be operative. It is universally believed that endotoxins are poor antigens. In cases in which antitoxin seemed to be helpful, it is believed that the antibacterial agents present in the preparation, not the antitoxin, were responsible. Two consultants alone feel that antitoxin might be of value in the severe fulminating case to neutralize quickly the hypothetical toxin.

Penicillin.—There may be no need at all for antibacterial serum if penicillin proves to be successful in treatment, either in replacing the sulfonamides entirely, which is unlikely, or for use in sulfonamide sensitive patients or for sulfonamide resistant meningococci. One investigator already reports success in this direction.

COMMENT

It is the consensus that sulfonamide therapy (sulfadiazine) is at present the method of choice in the treatment of meningococcic meningitis and septicemia. For the few patients who are sensitive to sulfonamides and for the still rarer instances of infection with sulfonamide resistant meningococci, the available potent, type specific horse antimeningococcic serum alone should be used intravenously, never intrathecally, in adequate dosage with promptness and precision. But because of the instances in which sulfonamides cannot be used with success there is no justification for the continued widespread manufacture, distribution and stocking of serum. A limited supply available at conveniently placed centers for prompt distribution would seem to be adequate. If proved by clinical trial to be as superior to horse serum as experiments now indicate, the use of concentrated, refined, monovalent serum prepared in rabbits should preferably be used, intravenously, never intrathecally.

There is no evidence to prove that combined chemosotherapy is superior to chemotherapy alone and no firm evidence to support the use of the meningococcic antitoxic serum which is now available. Further studies are needed to determine whether an endotoxin or exotoxin plays a role in the infection and whether a potent antitoxin can be made for successful use in fulminating cases.

Should penicillin prove to be successful in curing meningococcic meningitis and/or septicemia in patients who are sulfonamide sensitive or in whom the meningococci are or become sulfonamide resistant, there will be no further need for the use of antimeningococcic serum.

SUMMARY

Consideration of the available evidence revealed that few seem to be much concerned with the use of serum and that only in exceptional cases. It is also noted that the serum suggested (rabbit serum) is one which has never been submitted to the Council or, as far as is known, used clinically. Accordingly, the Council voted to omit Antimeningococcic Serum and Meningococcus Antitoxin from New and Nonofficial Remedies, the accepted preparations to be omitted at the end of the longest period of acceptance for any of these products.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AMERICAN MEDICAL ASSOCIATION HOLDS ANNUAL SESSION IN 1944

Announcement has been made officially that the American Medical Association will hold its 1944 annual session June 12-16 in Chicago. The House of Delegates will meet in the Palmer House, where the Scientific Exhibit and the Opening General Meeting will also be held. The Registration Bureau and the Technical Exhibits will be in the Hotel Stevens, and the meetings of the various sections will be assigned to these hotels and in addition to the Hotel Sherman and the Morrison Hotel.

A prospective feature of the annual session is a national medical war meeting at which there will be present distinguished representatives of the medical military services of the United Nations as well as other eminent speakers. The program and the place of this and other meetings will be announced as plans are completed. At the Conference of Section Secretaries with the Council on Scientific Assembly held in the headquarters of the American Medical Association in December, consideration was given particularly to salient features of the scientific programs. Plans were made for many round table and panel discussions and for symposiums on subjects of current interest, including such topics as the amino acids and the vitamins in nutrition, the dysenteries, postwar trends in obstetrics, industrial ophthalmology, new advances relating to the uses of penicillin and the sulfonamides, head injuries, asphyxia, the neuroses, fatigue, nutrition and rehabilitation, new aspects of endocrinology and urology, malaria and other tropical diseases, blood transfusion and new advances with blood and blood substitutes. A special section will be devoted to the interests of the general practitioner, and section officers have been appointed to work out a program designed particularly for this group. Already the applications for places on the program are sufficient to indicate the usual assembling of scientific discussions enhanced by new methods of presentation and exhibition.

Since the transportation and hotel facilities of Chicago are likely to be taxed to the utmost under war conditions, those who plan to attend the annual session should make the necessary reservations just as soon as the official announcement appears in the Organization Section of THE JOURNAL and in the advertising pages in the near future.

HIGH ALTITUDE FROSTBITE

Davis and his associates¹ call attention to some particular features of the frostbite incurred by airmen which differ from the features of frostbite incurred by ground forces during severe winter weather and from those of the frostbite of the immersion foot of shipwrecked seamen. Among the factors which contribute to the peculiarities of high altitude frostbite are the extreme degrees of cold encountered, such as minus 40 to 50 C., and the varying degrees of existing anoxemia and ischemia. Particularly noteworthy is the predilection of high altitude frostbite for the extremities, whereas the face and other exposed portions of the body are not affected. The great difference in cold tolerance between the tissues of the cheek and the fingers cannot be explained satisfactorily on the basis of the greater heat radiating surface of the fingers. Whereas the heat radiating surface per tissue mass in the fingers is three to four times greater than that in the cheek, the susceptibility to cold is fifty to one hundred times as great. Localized anoxemia resulting from the ischemia produced by intense reflex vasospasm of peripheral arterioles is probably the most important factor in establishing the peculiarly selective effect of cold on the digits of both upper and lower extremities. Exposure of one to two minutes suffices to render the fingers painfully cold, numb, stiff, waxy white in appearance and completely insensitive to touch. They feel hard and even brittle and cannot be flexed or extended voluntarily. The surface temperatures, as recorded by thermocouples, may be 4 to 6 degrees centigrade colder than the corresponding fingers of the unaffected hand. Capillary microscopy of the affected fingers in this early stage shows no blood in the terminal capillaries on the dorsum of the fingers about the nail beds. This would appear to be the result of an initial intense vasomotor spasm of the terminal portions of the arterioles and, in some instances, of a secondary thrombosis at the point where the arteriole passes into the capillary. The clinical types vary from mild to severe forms, the latter being described either as wet or as dry. The wet form is characterized by vesicles and dropsical blisters, the superficial layers of the skin becoming dissected away from the deeper layers by extravasated fluid. When

1. Davis, Loyal; Scarff, John E.; Rogers, Neil, and Dickinson, Meredith: High Altitude Frostbite: Preliminary Report, Surg., Gynec. & Obst. 77: 561 (Dec.) 1943.

this skin dries and hardens it is cast off, frequently in the form of a complete cast of the part. The dry type of high altitude frostbite cannot be differentiated in the early stage from the wet. However, it progresses to characteristic gangrene. The tissues shrivel and mummify and eventually become hard and coal black.

The basic morphologic lesion in high altitude frostbite, according to the authors, consists in damage by cold to the endothelium of the terminal capillary loops. In mild cases this results only in a pathologic permeability of the capillary walls; but in the more serious cases a thrombus formation occurs at the arteriolar-capillary junction. Davis found in severe cases a remarkable thickening of the intima of the vessels which resembles that seen in cases of endarteritis obliterans.

The authors experimented with protective ointments applied to the extremities of normal persons and of patients who had suffered injury from cold. Careful studies of skin temperature readings after controlled exposures yielded negative results. How much warmth should be applied to a frostbitten extremity during the early hours or days of treatment? Greene² insisted that frostbitten parts must be kept cool. He believed that the most favorable temperature was approximately plus 2 to plus 5 C. Application of heat to the frozen part, in his opinion, increased its metabolism and its oxygen requirement and encouraged the growth of bacteria. It also increased flow of blood to the parts, resulting in greater transudation and blistering. Davis and his associates treated a series of patients by keeping the damaged parts at controlled temperatures, approximating those advised by Greene, for periods ranging from twenty-four to forty-eight hours after the injury had been sustained. Simultaneously they also treated a second series of patients by exposing the damaged parts to room temperature. The results obtained by the latter method were equal to or better than those obtained by continued cooling. Attempts to accomplish peripheral vasodilatation by drugs such as amyl nitrite, glyceryl trinitrate, alcohol and acetylsalicylic acid administered both to normal persons and to patients with recent frostbites were likewise negative. The effect of these drugs on the peripheral capillary circulation was studied by means of electric thermocouples and through microscopy of the capillaries. None of the drugs caused an elevation of the temperature in the tested parts, nor did they cause a dilatation of the capillary bed. Blocking of the sympathetic nerve trunk and stellate ganglion with procaine hydrochloride was performed on patients suffering from acute vasoconstriction as a result of exposure to intense cold. Acute dilatation of the peripheral capillary bed could be effected in extremities in which there had not been permanent anatomic injury to the capillary wall or

thrombosis at the arteriolar-capillary junctions. When thrombosis or irreversible injury to the capillary wall had taken place, blocking of the sympathetic trunk and the stellate ganglion failed to produce either a rise in the temperature of the finger tips or a reappearance of blood in the terminal capillary beds.

THE SOVIET UNION AGAIN REVERSES ITS STAND, THIS TIME ON COEDUCATION

On June 27, 1936 the Central People's Health Committee of the Soviet Union passed a law prohibiting abortion except in the presence of stringent indications. Thus it completely reversed its stand of 1920, when it legalized artificial abortion. Simultaneously a number of measures calculated to lighten the burden of childbearing and induce the rearing of large families were proposed. Both Germany and Italy were, at the same time, encouraging the rearing of large families in their respective countries. One of the objections to the legislation, principally from Russian women, was that it represented an encroachment on the woman's right to determine whether she chooses to become a mother or not. As *THE JOURNAL* commented,¹ the attitude of the Soviet medical profession and in particular of the obstetricians and gynecologists was in sharp contrast to these views. According to one of the authorities (Professor G. A. Baksht) "The accumulated experience since 1920 furnishes abundant proof that an artificial abortion is a serious evil and that the operation even when performed *lege artis* leads to a number of injurious effects."

Now the Russians have decided to end coeducation in elementary and intermediate schools. Coeducation was introduced by the Bolsheviks not for any definite pedagogic reason but principally because it was to be one more step in the emancipation of woman and the accomplishment of sex equality. Now it is argued in favor of segregation that boys and girls do not develop physically and mentally along parallel lines at certain periods of their lives. Thus, the school program which the girl from 11 to 14 years of age can carry on with ease is too great a strain for boys of the same age, while the general capacities of girls from 14 to 17 years of age are somewhat lowered. There is also the necessity of a different educational approach to boys from that to girls in various phases of their development, the necessity of different presentation of material and of different methods of teaching and working. This differentiation cannot be obtained if boys and girls are in the same class. Then there is the inescapable division of labor between men and women. Women have responsibilities which do not apply to men, and those responsibilities are of crucial importance in the survival of the nation. Women are

2. Greene, Raymond: Frostbite and Kindred Ills, *Lancet* 2: 689 (Dec. 6) 1941.

1. The Soviet Union Reverses Its Stand on Legalized Abortion, editorial, *J. A. M. A.* 107: 1391 (Oct. 24) 1936.

mothers, and they must be able to look after children and to rear them. Separate education will result, among other things, it is believed, in strengthening the Soviet family. The emphasis on training for motherhood and rearing of families suggests that the motivating factor behind this measure is a long range program for increased manpower. This supposition finds support in the fact that Russia has reputedly lost some 17,000,000 of her population in the present holocaust.

Coeducation has fared well in the United States; few pedagogues of any importance clamor for segregation. Moreover, there has been a persistent increase in the birth rate to 24 per thousand of population with 3,200,000 births in 1943, an excess of more than 200,000 over 1942. What will be the results of this new experiment in the Soviet Union? The experimental approach to social problems, whatever the motivation, holds a greater promise than rigid adherence to the tenets of Marx or any other philosopher in the field of government.

Current Comment

FLUORIDE AND DENTAL CARIES

The protective action of fluoride against dental caries was first indicated by epidemiologic studies¹ which disclosed an inverse relationship between the prevalence rates of dental caries and the fluoride concentration of the municipal water supplies. Relatively low incidence of caries was found associated with the use of domestic waters whose fluoride concentration had a range of one or more parts per million.² Next, laboratory studies³ revealed that salts of fluoride could inhibit the experimental production of caries in the molar teeth of rats. On the basis of this evidence, clinical investigations were undertaken in an attempt to control dental caries by the prophylactic and therapeutic use of fluoride salts. A method was devised by Cheyne⁴ for the topical application of fluoride to the teeth without the attendant danger of its systemic ingestion or absorption. Briefly, the method consists in thorough cleaning of the teeth, which are then isolated by means of cotton rolls and dried with compressed air. A solution of sodium fluoride is then applied to the crown surfaces of the teeth and allowed to remain in contact with the surfaces for at least two minutes, during which the solution is dried. The effectiveness of this therapy was analyzed by Cheyne in a group of 27 children with carious deciduous teeth as compared to a control group with similar lesions who did not receive treatment. After a three months period dental exami-

nation showed that the treatment had effected a 50 per cent reduction in the incidence of dental caries and had been equally effective in suppressing carious activity in the preexisting lesions. This observation was confirmed by Bibby⁵ with the topical application of 0.1 per cent solution of sodium fluoride to one quadrant of the mouth, using the other side of the same jaw as control. A 40 per cent reduction in the activity of caries in the treated quadrant was observed in a group of 78 children periodically examined for two years after the treatment. Knutson and Armstrong⁶ more recently have used the same procedures, applying topically a 2 per cent solution of sodium fluoride. Two hundred and eighty-nine treated children, as compared to 326 control children, exhibited a reduction of 40 per cent in the incidence of dental caries. In this group the treatment was ineffective in preventing new attacks by caries on teeth already attacked, which was taken as an indication that the method was without effect in the control of active dental caries. As the analysis of activity in caries is dependent on a highly subjective criterion, further data will be required in order to warrant any definite statement as to the therapeutic effect of fluoride. Further, as an excess of fluoride is bound to produce chronic dental fluorosis, commonly known as mottled enamel, it is necessary to determine the minimum effective concentration of the element which will prevent carious lesions without at the same time injuring the teeth.

THE FIRST CANCER CONGRESS OF MEXICO AT GUADALAJARA

In these times, when inter-American relations are so important, the organization of a cancer congress by Mexico was timely. It brought together medical men of different American nations and gave them an opportunity of getting first hand information about interesting scientific developments in the Mexican republic. Mexican medicine is now at a transitional stage in many ways comparable to that of the United States several decades ago. Contrast is everywhere in Mexico. Whereas some Mexican clinical or scientific institutions are primitive, others are as up to date as the most modern institutions of this country—such as the institutes of cardiology, pediatrics and public health of Mexico City. One must add the magnificent units built by the Spaniards in colonial times, such as the orphanage in Guadalajara, which is still in perfect condition and is still serving its purpose. Whereas research in cancer, for instance, is yet in an elementary stage, the Mexican investigations in rickettsial diseases are among the most brilliant in the world. Although some of the surgical institutions may be faulty as far as organization is concerned, the operative skill of the Mexican surgeon is amazing. The cancer congress reflected the present stage of Mexican medicine. Whereas contributions to the theoretical side of the problem were few, the clinical papers were numerous

and of good quality. Some consisted of reviews of the different types of cancer, especially useful for the general practitioner and also for students, who attended the sessions in large numbers. Several of these lectures were given by Americans, forty of whom, mostly from the Southern states, attended the congress. Dr. R. R. Spencer, director of the National Cancer Institute, gave a paper on the program of work conducted at Bethesda, Md., while comparable papers on cancer control were read by Drs. Baeza and Valdés. Operative clinical sessions were held every day and proved the statement concerning the high level of Mexican surgery. The congress was organized by its president, Dr. G. Vazquez Arroyo of Guadalajara. It was sponsored by the president of the republic and by federal and state authorities and was supported by a large grant from the Mexican government. The program of entertainment was varied and was conducted with characteristic generosity. In the closing session Monterrey was selected as the place for the celebration of the second Mexican Cancer Congress, in 1945.

MEDICAL SCIENCE CENTER FOR DETROIT

Under the auspices of the board of directors of Wayne University in Detroit a project is now under way to create a \$50,000,000 Medical Science Center to be built around Wayne University's College of Medicine. The proposal involves the erection of a dozen buildings including a library of medical sciences, new buildings for the schools of medicine, dentistry, pharmacy and nursing and allied subjects, an institute for graduate study and an institute of industrial health. The population and the characteristic industries of the city of Detroit unquestionably make it an excellent location for a great medical center and particularly for an institute of industrial health. The advances of modern medical science make necessary renovation and rebuilding of laboratories. The need for a medical center in Wayne County has long been recognized. A 53 acre site has been earmarked adjacent to the hospitals and medical office buildings of Detroit, and a special nonprofit corporation has been developed to raise the necessary funds and to guide the development of the new institution. The first unit—namely, the hospital—is to serve patients requiring public assistance and will be erected by Wayne County. No doubt the city and state will find it convenient to develop their medical care program in relationship to this medical center. Unique, however, is the proposed institute of industrial health. A few of our great universities now offer courses in this field, and many of the state medical societies, led by the Council on Industrial Health of the American Medical Association, have provided study in industrial health. Detroit is recognized as an industrial capital. Many of its great industries have already developed units in preventive and industrial medicine which have contributed to research and progress in this field. The concept of an industrial health institute as a part of a medical science center deserves all the encouragement that the medical profession can give.

THE AMERICAN MEDICAL ASSOCIATION AND THE NATIONAL PHYSICIANS' COMMITTEE

A statement released by Senator James E. Murray of Montana, whose name is familiar to physicians as one of the participants in launching the Wagner-Murray-Dingell bill, charges that the American Medical Association has set up a committee in Chicago which is sending out a huge amount of propaganda intended to distort and falsify the bill and cites a pamphlet published by the National Physicians' Committee. Simultaneously with this release Dr. E. H. Cary, president of the board of the National Physicians' Committee, issued a statement to the effect that the committee "is in no way connected with the American Medical Association except in that it is a committee of physicians and the physicians are members of the Association." From the headquarters office a statement was issued to the effect that "there is no connection whatsoever, officially or in the form of financial support, between the American Medical Association and the National Physicians' Committee, except that the House of Delegates of the American Medical Association has given its approval to the efforts not only of the National Physicians' Committee but of any other reputable organization that will aid in defeating this pernicious legislation." Senator James E. Murray would render the American people a better service by making certain of the alleged facts before making unwarranted charges. The proponents of the Wagner-Murray-Dingell bill must find the going tough if it is necessary to support it by this type of propaganda.

PENICILLIN IN THE TREATMENT OF RELAPSING FEVER

Relapsing fever is a tick or louse borne spirochetal infection which occurs endemically in most countries. With overcrowding and poverty, relapsing fever may become epidemic. According to the League of Nations report, more than 1½ million cases were observed in European Russia the year following World War I. Arsenic, usually arsphenamine, is said to be the most effective therapeutic agent. The occasional development of arsenic resistant spirochetes, the frequency of relapses and the hazards and complications which occur after arsenical therapy are disadvantages. The search for a more desirable agent has been made by Heilman and Herrell, who studied the effectiveness of penicillin against relapsing fever experimentally produced in mice by a single strain of *Borrelia novyi*. Although 100 Oxford units of penicillin per cubic centimeter did not cause a visible decrease in motility of spirochetes in vitro, 1,000 units to heavily infected mice was associated with their complete absence in the blood smear in two to three days. Of 26 treated mice only 1 (1 per cent) died, whereas in the control group 21 out of 27 (75 per cent) died. All untreated mice which survived exhibited relapses, while only 4 of the treated mice had a relapse. As the strains of the spirochete which produce relapsing fever are closely related, it is likely that penicillin will be effective also against other strains of this organism.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeons General of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession.

ARMY

THE CALIFORNIA-ARIZONA MANEUVER AREA

The California-Arizona Maneuver Area, formerly known as the Desert Training Center, is organized as a training theater of operations with all functions of combat, supply and service paralleling as closely as possible like functions in an overseas theater of war. Medical service, including evacuation of actual sick and injured from maneuvering combat troops, is performed in a realistic manner by use of medical battalions, field and evacuation hospitals and finally general hospitals. There are three general hospitals in operation at present exclusively for California-Arizona Maneuver Area troops. These are theater of operation type construction, 1,000 bed rated capacity and staffed by numbered general hospital units. These numbered units operate the hospitals for approximately three months to give them necessary experience and training to qualify them for overseas assignment. The three general hospitals are located as follows and operated by the units indicated:

Beaumont, Calif., 22d General Hospital:

Lieut. Col. Adrian G. Gould, M. C., commanding officer.
Major Clarence H. Rommel, M. C., executive officer.
Major Emmet F. Pearson, M. C., chief of Medical Service.
Major Foster L. Dennis, M. C., chief of Surgical Service.
Lieut. Col. Elton E. Hankins, D. C., chief of Dental Service.
Lieut. Col. Frank T. Moore, M. C., chief of X-Ray Service.
1st Lieut. Bernard Stempel, M. C., chief of Laboratory Service.

Spadra, Calif., 34th General Hospital:

Col. Walter L. Richards, M. C., commanding officer.
Major Myron S. Jared, M. C., executive officer.
Major Barnard Davis, M. C., chief of Medical Service.
Lieut. Col. William B. Schaefer, M. C., chief of Surgical Service.
Major Kyle L. Rose, D. C., chief of Dental Service.
Capt. Thomas W. Knickerbocker, M. C., chief of X-Ray Service.
1st Lieut. William B. Chamberlin, M. C., chief of Laboratory Service.

Banning, Calif., 297th General Hospital:

Col. Francis W. Pruitt, M. C., commanding officer.
Major Gordon E. Snyder, M. C., executive officer.
Lieut. Col. George F. O'Brien, M. C., chief of Medical Service.
Lieut. Col. Chester C. Guy, M. C., chief of Surgical Service.
Lieut. Col. Joseph L. Uhl, D. C., chief of Dental Service.
Major Elbert K. Lewis, M. C., chief of X-Ray Service.
Lieut. Col. Alex B. Ragins, M. C., chief of Laboratory Service.

DISPOSITION OF PERSONS WITH NEUROPSYCHIATRIC DISORDERS

Circular Letter No. 194, issued December 3 by the Office of the Surgeon General, is concerned with the disposition of persons with neuropsychiatric disorders. At the present time over 45 per cent of the certificate of disability discharges are for neuropsychiatric reasons. The importance of eliminating actual or potential neuropsychiatric noneffectives has not diminished. However, the possibility must be considered that neuropsychiatric criteria for service are now being interpreted too strictly and men are being separated from the service who could be of value were they retained. Each case must be evaluated individually and disposition made on the basis of clinical judgment as to the individual's potential value to the service. It is well established that a large proportion of men developing psychiatric disorders, particularly in combat zones, if properly treated and promptly returned to duty, recover entirely and render valuable service. Any one, no matter how sound his personality,

may develop a psychiatric disorder under certain circumstances and will recover, if properly treated, when these circumstances are changed or when he has had an opportunity to adjust to them. An attempt should be made in each case to determine when the psychiatric disorder is merely the natural result of fatigue, misassignment or a distressing situation, or whether it is a manifestation of fundamental neuropsychiatric unsuitability for military service. Where the psychiatric disorder is believed to arise more from indifference toward the war than from fundamental instability of personality, the individual will be retained for service. Disposition of neuropsychiatric cases may be any of the three following:

1. *To full duty.* Individuals who, after careful study by examining medical officers, are believed to be of potential value at full duty in combat zones regardless of the psychiatric diagnosis which has been made will be returned to duty.

2. *To duty of less arduous nature than full duty in combat zones.* Individuals who, after careful study by medical officers, are believed to be noneffective for combat duty but potentially capable of serving in less arduous assignment, either in continental United States or overseas, will be returned to duty with a recommendation to this effect.

3. *Separation from the service.* (a) Individuals who, after careful study, are believed to be of no further value to the service because of the presence of psychosis, psychoneurosis, epilepsy or organic neurologic disease will be separated from the service under the provisions of section II, AR 615-360. (b) Individuals who, after careful study, are believed to be of no further value to the service because of the presence of mental deficiency, psychopathic personality or primary behavior disorders (such as chronic alcoholism or drug addiction) will be discharged under the provisions of section VIII, AR 615-360.

ELIMINATION OF UNNECESSARY LABORATORY WORK

The Office of the Surgeon General issued on November 30 Circular Letter No. 193, which is concerned with the elimination of unnecessary laboratory work. There has been a tendency on the part of section chiefs and ward officers in both medical and surgical sections to order laboratory work much beyond the actual need for the adequate care of patients. In view of the shortage of qualified laboratory personnel it is essential that laboratory work be reduced to a minimum. Reduction is desired in the following procedures, which appear to be carried out on an excessive scale at present: (1) blood cell counts, especially red cell counts and leukocyte differentials, (2) microscopic examination of urine, (3) bacteriologic cultures when smear examinations are diagnostic, (4) routine and repeated blood chemistry studies when the nature and course of the disease are clearly evident, (5) routine serologic tests for syphilis on admission and (6) sputum and stool examinations in individuals without symptoms of pulmonary or gastrointestinal disease. X-ray films, which are frequently made routinely, are not to be made when there is no clinical reason to suspect disease in the part x-rayed.

It is not intended that work essential for diagnosis and estimation of progress be curtailed. Prior to surgical operation, leukocyte counts, hemoglobin determinations and urinalyses are considered essential. Blood smear examinations for malaria

are of current great importance in the case of men returning from areas where malaria is endemic; search for parasites should be made carefully in this group. So that unnecessary work may be eliminated, individual consideration should be given to cases in determining the need for laboratory examinations.

This letter does not apply to examinations for induction, appointment and discharge, in which chest x-ray examination and certain laboratory tests are required.

FIFTIETH ANNIVERSARY OF THE ARMY MEDICAL SCHOOL

The Army Medical School, located at the Army Medical Center, Walter Reed General Hospital, Washington, D. C., marked its fiftieth anniversary December 18 with the award of certificates to the sixteenth class in military and tropical medicine to be graduated since August 1941. Col. Richard P. Strong, director of tropical medicine at the Army Medical School, presented certificates to the 124 graduates, which included officers of the Army of the United States, the Canadian and Peruvian armies, and officers of the state health departments. Major Gen. Norman T. Kirk gave the graduation address. Participating also at the graduation exercises, were Major Gen. Shelley U. Marietta, commanding general of the Army Medical Center, and Lieut. Col. Thomas T. Mackie, executive officer of the course.

The fiftieth anniversary of the founding of the Army Medical School in 1893 was commemorated by a brief ceremony presided over by Col. G. R. Callender, director of the school, and honoring Col. Deane C. Howard, who ranked first in the initial class to be graduated and who was retired in 1922. Colonel Howard was chief of the Division of Sanitation in the Office of the Surgeon General during World War I and holds the Distinguished Service Medal.

MEDICAL MEETINGS IN NORTH AFRICA

The 45th General Hospital, which was organized from the faculty of the Medical College of Virginia, Richmond, began holding medical meetings shortly after its arrival in North Africa. The meetings, which have been held the second and fourth Thursday of the month since April, have all been arranged by Major Guy W. Horsley, chief of the surgical service. The speakers and subjects have been varied, and many of the talks have been on personal experiences of the speakers in many corners of the world. One meeting was devoted to the experience of medical officers in the Tunisian campaign, another to the removal of foreign bodies, another to experiences in the Belgian Congo with tropical diseases, and still another to the experiences of the commanding officer of an infantry regiment with his medical troops in the Sicilian campaign. Invitations to attend these meetings are extended to all medical officers both in hospitals and attached to troops through notice published in the daily bulletin of the base section where this hospital is located. The 45th General Hospital will continue to hold these meetings, which have been well attended and have proved a great success, throughout its stay overseas.

MAJOR GEORGE W. BEELER AWARDED LEGION OF MERIT

The Legion of Merit was awarded to Major George W. Beeler, formerly of Texas City, Texas. The citation accompanying the award read as follows: "Capt. George W. Beeler, medical corps, United States Army, for exceptionally meritorious conduct in the performance of outstanding services during the period from Jan. 1 to Feb. 28, 1943, at Guadalcanal. As chief of the surgical service of a field hospital, operated by a medical battalion, Capt. Beeler successfully performed innumerable surgical operations requiring the highest degree of skill. He also was responsible in a large degree for the excellent surgical care of the patients of the field hospital, which averaged 350 patients constantly over a three month period. He worked untiringly to care for the needs of the wounded." Dr. Beeler graduated from the University of Texas Medical Branch, Galveston, in 1932 and entered the service in September 1941.

LIEUT. COL. WILLIAM C. MENNINGER APPOINTED CHIEF OF NEUROPSY- CHIATRIC BRANCH, SURGEON GENERAL'S OFFICE

The War Department recently announced the appointment of Lieut. Col. William C. Menninger as chief of the neuropsychiatric branch in the Office of the Surgeon General. He will fill the vacancy created by the death of Col. Roy D. Halloran, who died November 10 (THE JOURNAL, Nov. 20, 1943, p. 786). The primary objectives of the Army's neuropsychiatric service are to screen out at induction or eliminate later men whose mental instability is such as to render them unsuitable for combat or other duty, to aid in maintaining discipline and morale among all troops and to treat and rehabilitate men suffering from nervous disorders incurred in military service. Dr. Menninger graduated from Cornell University Medical College, New York, in 1924. He has been neuropsychiatric consultant for the Fourth Service Command since he was called to active duty Nov. 10, 1942.

CAPT. VICTOR V. VARE RECEIVES SILVER STAR MEDAL

Capt. Victor V. Vare, formerly of Jamaica, N. Y., and now serving somewhere in Italy as a surgeon with a tank battalion, received the Silver Star award for "devotion to duty." The citation accompanying the award read as follows: "For professional work and an excellent job in preoperative and post-operative cases, treatment, shock therapy and unstinting devotion to duty without regard for fatigue and loss of sleep. It is difficult to see how this officer got any sleep or rest for the first four days. The chiefs of the surgical teams wish to convey to you their sincere thanks and appreciation for the cooperation and help accorded in all respects during a trying period." Dr. Vare graduated from Columbia University College of Physicians and Surgeons in 1941. He was ordered to active duty on July 1, 1942 and was trained at Carlisle Barracks, Pennsylvania, and Camp Edwards, Massachusetts, before being sent overseas last April.

LIEUT. COL. JOHN M. SNYDER AWARDED LEGION OF MERIT

The War Department announced recently an award of the Legion of Merit to Lieut. Col. John M. Snyder, formerly of Slatington, Pa., for "exceptionally meritorious conduct in the performance of outstanding services from March 19 to April 8, 1943. On many occasions Lieutenant Colonel Snyder, chief of surgical service, worked unceasingly at the operating table until exhausted and then after only two hours of rest would continue his duties. The fidelity to his task and the calm and tenacious manner in which he performed his duties were a fine example and an inspiration to all with whom he came in contact. Lieutenant Colonel Snyder's performance of duties exemplifies the highest traditions of military service." Dr. Snyder graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1934 and entered the service March 12, 1941.

TWELFTH CLASS OF AVIATION PHYSIOLOGISTS

Graduation exercises at the School of Aviation Medicine, Randolph Field, Texas, for the twelfth class of Aviation Physiologists was held November 27. The course in aviation physiology is of five weeks' duration and treats of the effects of flight on man, the operation of low pressure chambers, the theory and practical use of oxygen equipment and the conduct of high altitude indoctrination and classification. Brig. Gen. Eugen G. Reinartz, U. S. Army, is commandant of the school. Among those graduating were 1st Lieut. Joseph H. Holmes, New York, and 1st Lieut. Jacob M. Werle, Cleveland, of the medical corps.

FAMOUS FOOTBALL COACH NOW STUDENT AT MEDICAL FIELD SERVICE SCHOOL

Major Edward N. Anderson, former head football coach at the University of Iowa, is a student officer at the Medical Field Service School, Carlisle Barracks, Pennsylvania, where in a six weeks course he will be taught the military knowledge necessary for him to be an efficient officer, capable of carrying out medical preventive measures and caring for the sick and wounded under war conditions. Although a physician by profession, Dr. Anderson has played and taught football for nearly two decades. He is a graduate of Rush Medical College, Chicago, 1929. During the off seasons Dr. Anderson has followed his medical profession and has done considerable research work in the interest of medicine. He received his commission in February 1943.

CAPT. MARY C. WALKER TO SUPER- VISE CADET NURSES

Capt. Mary C. Walker, Army Nurse Corps, former assistant director of the Colorado State Board of Nurse Examiners, has been named to supervise U. S. Cadet Nurses entering army hospitals for six months' affiliation and training. Under the training and orientation program, in which approximately thirty army hospitals will participate, the students, all senior cadets, voluntarily take the six months army course, after which they assume either civilian or military nursing duties. While taking the army course they will be provided by Captain Walker with qualified army nurses as educational directors and clinical instructors. Every ten senior cadets affiliated with the army can relieve eight army nurses for overseas duty, Captain Walker explained.

TREATMENT OF VENEREAL DISEASE IN ARMY HOSPITALS

The treatment of venereal disease in army hospitals was recently discussed in Circular Letter No. 195, issued December 1 by the Office of the Surgeon General. Regardless of the specific type of venereal disease, the hospital management of patients with venereal disease ordinarily entails the use of diagnostic, epidemiologic and administrative procedures which are similar. In order to insure that these functions are well coordinated, the organizational charts for station and general hospitals will provide for a Venereal Disease Section. Since ordinarily each of the venereal diseases is now effectively treated by internal medication, making surgical or manipulative procedures rarely necessary, the Venereal Disease Section should be organized as a unit of the medical rather than the surgical service. In hospitals under construction and subsequently authorized, the staff organization will conform initially to this policy; in existing hospitals where the Venereal Disease Section is not already a unit of the medical service it will be transferred thereto unless, because of local conditions, such transfer would clearly be prejudicial to the most efficient care of patients with venereal disease.

FIRST WOMEN DOCTORS GO THROUGH TRAINING

The Army's first women doctors are going through their indoctrination and training at Lawson General Hospital, Atlanta, Ga., prior to their assignment to fixed medical installations. Ten doctors are in the four weeks course learning army medical procedure and administration. At the completion of the course they will replace male doctors for overseas service.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

INTERNSHIPS AND RESIDENCIES

The Directing Board of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians issued Form No. 317, dated December 22, to the state chairman for physicians, which is concerned with the approval by state boards of licensure of nine months' internship. The Federation of States Boards of Medical Licensure communicated with all states requiring the prerequisite of an internship for licensure to practice medicine. Every state and territory approved the nine months internship for commissioned officers, accepting either general military service or service in a military hospital of three months to make up for the entire internship of a year. A number of states did not approve the nine months internship for persons ineligible for military service. All interns not going to the service, therefore, should be told to serve an additional period of nine months as a junior resident, so as to qualify for the minimum internship requirements of some states. This is a means by which more physically disqualified men may be encouraged to take residencies.

RELOCATING PHYSICIANS AND DENTISTS DISCHARGED FROM THE ARMY

Arrangements for the relocation of physicians and dentists discharged from the army are explained in Form No. 316 recently issued by the Directing Board of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians. The Veterans Employment Service, a division of the War Manpower Commission's Bureau of Placement, has a field staff which spends a considerable part of its time in hospitals from which soldiers are discharged in order to facilitate their return to civilian life. This field staff has now been instructed to work closely with the Procurement and Assignment Service in assisting discharged physicians and dentists to return to private practice. It is hoped that, as a result of this joint effort, physicians and dentists may be directed to critical areas and to other

places where they can free men for military service who are now essential to their communities. The names of physicians and dentists approved for discharge will be furnished the Veterans Employment Service field staff by the army officials at hospitals from which discharges from service are made. The field staff will interview these physicians and dentists and will give the central office the following information for forwarding to the state chairmen:

1. Name, specifying whether M.D. or D.D.S.
2. Address of former place of practice or position, if any.
3. Address of contemplated place of practice, if definite decision has been made.
4. Type of practice.
5. State in which he is licensed to practice.
6. Exact date of discharge, if possible, or approximate date of discharge.
7. Address where he may be reached the following ten days.
8. Opinion of the individual as to when he will be able to practice.
9. Opinion, if possible, of the medical officer in the hospital as to the physical and mental condition of the individual, and when he will be able to undertake the practice of medicine or dentistry. (This information, of course, will be kept strictly confidential.)

Those persons who know where they intend to practice will be instructed to get in touch with the state chairman so that he may be informed. Procedures for effecting the relocation of other persons who have not made a definite decision have not yet been completely worked out. Methods for solving the many problems involved in returning veteran physicians and dentists to civil life will have to be worked out as the program develops. The Procurement and Assignment Service, however, has a definite responsibility to these veterans, as well as a continuing responsibility for furnishing physicians to the armed forces, having due regard for the medical needs of the civilian population.

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

An extensive schedule of courses of instruction under the auspices of the Wartime Graduate Medical Meetings in Region 3 in New York has just been announced. The regional committee consists of Dr. Oswald R. Jones, Dr. Norman Jolliffe and Dr. Henry W. Cave. The schedule of courses at the Grand Central Palace, 480 Lexington Avenue, New York, is as follows:

January 14, Dr. Elbert Vander Veer, The More Frequent Allergies.
January 21 (repeated January 28), Dr. Harold E. B. Pardee, Significance of Normal and Abnormal Electric Cardiographic Tracings.
February 4 (repeated February 11), Dr. Algernon B. Reese, External Diseases of the Eye and Glaucoma.
February 18 (repeated February 25), Dr. William P. Thompson, Simple Laboratory Procedures.
March 3 (repeated March 10), Dr. Alan DeForest Smith, Foot Strain.
March 17 (repeated March 24), Dr. George C. Andrews, Common Skin Diseases in Soldiers.
March 31 (repeated April 7), Dr. A. Wilbur Duryee, Peripheral Vascular Disease.
April 14 (repeated April 21), Dr. John F. Erdmann, General Surgical Approach to the Abdomen.
April 28 (repeated May 5), Dr. Arthur Krida, Disorders of the Low Back.
May 12 (repeated May 19), Col. Douglas T. Thom, Neuropsychiatric Problems in the Army.

The schedule of courses to be given at Camp Shanks, Orangeburg, N. Y., is as follows:

January 13, Dr. Arthur H. Fishberg, Nephritis.
January 20, Dr. John B. Dunnington, Medical Ophthalmology.
January 27, Dr. George C. Andrews, Common Skin Diseases in Soldiers.
February 3, Dr. Byron Stookey, Low Back Pain and Sciatic Syndrome: Discussion of Causes and Treatment.
February 10, Dr. A. Benson Cannon, Syphilis.
February 17, Dr. J. Burns Amberson, Sequela of Acute Pulmonary Conditions.
February 24, Dr. C. Cary Eggleston, Rheumatic Cardiac Disease, Diagnosis and Treatment.
March 2, Not announced.
March 9, Dr. Robert Loeb, Present Status of Human Serum Albumin and Plasma.
March 16, Not announced.
March 23, Dr. Herbert Chasis, Hypertension.
March 30, Not announced.
April 6, Dr. Frank L. Meleney, Surgical Bacteriology in the Treatment of Surgical Infections.
April 13, Dr. Walsh McDermott, Present Status of Use of Sulfonamides in Surgery and Medicine.
April 20, Dr. Emery A. Rovenstine, Anesthesia.
April 27, Col. William C. Porter, Neuropsychiatric Problems in the Army.

On January 6 Dr. Dana Atchley gave the first lecture in this series on Medical Shock.

CHIEF MEDICAL OFFICER OF PHYSICAL REHABILITATION

Mr. Paul V. McNutt, federal security administrator, recently announced the assignment of Dr. Dean A. Clark, surgeon, U. S. Public Health Service, as chief medical officer of the Office of Vocational Rehabilitation to take charge of the newly established Physical Rehabilitation Section. In commenting on Dr. Clark's appointment, Mr. Michael J. Shortley, director of vocational rehabilitation, said that the use of federal funds for remedial medical treatment of the physically handicapped was authorized for the first time under the Barden-LaFollette act of July 6, 1943. He explained that the new vocational rehabilitation program will make an important contribution to the war effort by facilitating the employment of the physically handicapped and thus promote effective use of manpower for war work. The rehabilitation program is designed to assist all physically handicapped individuals to obtain remunerative employment, except veterans with service connected disabilities, who come under the program directed by the Veterans Administration. The program is operated by the states through their boards of vocational education and their official agencies for the blind.

As a war measure the federal government pays the full cost of rehabilitating war disabled civilians. These include officers and crew members incapacitated while on war duty in the merchant marine and members of the Aircraft Warning Service, Civil Air Patrol and U. S. Citizens Defense Corps.

The federal government pays half the cost of rehabilitation for other individuals. All administrative expenses of the states in conducting approved rehabilitation programs are also met with federal funds. Under the new statute, federal aid may be utilized to provide all types of medical and surgical services necessary to modify a physical condition which is static and which constitutes a substantial handicap to employment. Conditions for which medical services are undertaken must, however, be of such a nature that treatment may be expected to eliminate or substantially reduce them within a reasonable length of time. Hospitalization not to exceed ninety days may also be furnished as well as prosthetic appliances essential for obtaining or retaining employment.

Dr. Clark graduated from Johns Hopkins University School of Medicine, Baltimore, in 1932.

CHILEAN ARMY DOCTORS INSPECT NATIONAL NAVAL MEDICAL CENTER

Two Chilean army doctors, Col. Flavio Meza Olva, prospective surgeon general of the Chilean army, and Major Ramon Vicuna Herboso, surgeon attached to the army headquarters, recently completed a tour of inspection of the Naval Medical Center, Bethesda, Md., and the Army Medical Center, Washington, D. C., during which Dr. Vicuna contributed his blood for the American armed forces "as a symbol of amity between the army of Chile toward the American army." Dr. Meza was formerly professor of medicine at the University of Chile, and Dr. Vicuna is now professor of medicine. The two medical officers arrived in this country December 5 on a medical mission sponsored by the Coordinator of Inter-American Affairs. They will study military medicine and civilian teaching methods in various sections of the United States.

PUBLIC HEALTH UNDER HITLER

Psyche Paychev reports in *Slovo* (Bulgaria) of Oct. 1, 1943 that the state of hygiene in restaurants and other food producing establishments is deplorable. After stressing the need for more cleanliness, he writes: "One must acknowledge that, owing to the nonexistence of continuous and strict sanitary supervision, the reality is very dark. Everybody who has occasion to enter the kitchens of restaurants and hotels and of shops where sweets, milk or bread are produced or where food is canned will be bewildered and disgusted by the dirt and lack of hygiene reigning there. In most of such concerns, kitchen workers are disgustingly dirty, awful to look at, and wear no overalls. Copper vessels have not been tinned, and all vessels are extremely dirty. The food is always covered with flies and creeping insects. I leave it to the imagination of the readers to decide what the products are like. In certain shops the tablecloths and towels are dirtier than the puttees of soldiers in the front line. What we have just said is not a myth but reality itself which may be checked at any moment. That is why we ask for stricter sanitary control."

According to *Novo Vreme* (Yugoslavia) of Oct. 1, 1943 the state of contagious diseases in Belgrade during the last month shows certain changes: The influx of typhus still continues. The number of reported cases of typhus last month is 7, which is the same as the month before last. Typhoid shows a seasonal increase, that is to say there are 25 new cases against 13 for the month before last. Scarlet fever shows an increase, always in the beginning of the school year, but there are no serious cases. Diphtheria has also increased, with 87 cases compared with 58 in August. All schools and children's organizations have received orders to take the most energetic countermeasures in connection with this increase. Malaria, as the chief seasonal illness, shows a pronounced decrease; in September there were 415 cases recorded, as compared with 999 in the previous month. Antimalarial activity, which gave such good results in August, has been continued, but on a somewhat reduced scale. A large number of springs have been chlorinated.

ORGANIZATION SECTION

OFFICIAL NOTES

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS OF CONSTITUENT STATE MEDICAL ASSOCIATIONS

FRIDAY, NOVEMBER 19—MORNING

Dr. Roger I. Lee, Chairman of the Board of Trustees of the American Medical Association, welcomed the conference.

Dr. John S. Bouslog of Denver was elected chairman.

Address by Dr. James E. Paullin, President of the American Medical Association

During the past ten or twelve years it has been my pleasure to have been intimately associated with the activities of the office of the American Medical Association here in Chicago. I think some of us, unfortunately, get the idea that the headquarters office is an institution which is set apart from the state associations, whereas it is your office, and it is conducted according to the policies and instructions given to it by the House of Delegates of the American Medical Association. The headquarters office makes every effort to carry out the policies which have been determined for it to follow.

At this time I should like to bear witness to the faithfulness with which the Board of Trustees handles the affairs of the Association. During the past two years it has been my pleasure to meet with them on many occasions, and I have never seen a group of men more earnest and who have devoted more attention to the business of the association.

What I say concerning the Board of Trustees is true for every member of the councils and bureaus in this organization. All of you are familiar with the efforts of two of our staff, in particular, who really supply the inspiration for the activities of the headquarters force. No words of praise are too many to be given to the untiring, unselfish work of Drs. Olin West and Morris Fishbein.

During the past year the Association has been extremely active in attempting to look into the future concerning many problems that face us. The House of Delegates directed that the Wartime Graduate Medical Training Program should be instituted as a part of the activities of the American Medical Association, in cooperation with the American College of Surgeons and the American College of Physicians. The accomplishments of this committee, with the help of a long list of honorary consultants drawn from civilian practice and from the military service, in making available the latest developments of scientific medicine to physicians in military and civilian practice throughout the United States, is a record of which we are proud. The appreciation with which these programs have been received by all is a tribute to the foresightedness and to the planning of the House of Delegates, in making possible this contribution of American Medicine in the fulfillment of our desire to be of greater helpfulness in stimulating an interest for postgraduate teaching among military and civilian physicians.

The Postwar Planning Committee has held several meetings. There are problems which have been discussed by this group which should be of interest to you; first, problems that directly concern us in this country; second, problems which will concern us after the war is over, in our relationship to the countries of our allies.

One of the problems about which there is much discussion is that of supplying physicians to meet civilian needs for medical care. With the adoption of the accelerated medical training program by the Army and Navy, in which there will be allotted about 20 per cent of the available places in medical schools for physicians to be used in supplying civilian needs (the 20 per cent to be composed of men deferred by Selective Service, those physically disqualified for military duty and women) it is evi-

dent that under the most favorable circumstances this would give only about 1,200 graduates each twelve months to meet the demand. If conditions remain as they are now, with no change in the mortality rate of doctors over 40 years of age who are engaged in civilian medical practice, there will be an annual deficit of nearly 2,000 physicians. It isn't believed that the 1,200 graduates each year allotted to civilian medical care can be placed in this essential capacity. Of the women graduates some will undoubtedly join the Army or Navy, and industry will claim many others. Should the war last beyond 1945 this shortage will become a very serious problem, even though many of the physicians discharged from the military service will enter private practice. This will not be sufficient to meet the deficit caused by deaths and retirement.

Another problem which concerns us is that of providing for the 20,000 physicians who will be anxious to begin the practice of medicine when the war ends. Of this number some have never engaged in the private practice of medicine; some entered the military service after a brief nine months internship, others after a longer period of training either as a resident or as a fellow. A postwar planning group, utilizing the facilities of the Council on Medical Education and Hospitals, the Bureau of Medical Economics of the American Medical Association, together with the Procurement and Assignment Service, in cooperation with state and county medical societies can be most helpful in organizing a program for the better distribution of physicians into areas where they are most needed and in making suggestions to communities which would make many of them more attractive to the well trained young physician to begin the practice of medicine.

Many of the younger men returning from military service will feel the need of additional training or instruction before undertaking medical practice. Some will desire refresher courses to equip them for general practice; others will want a longer period of training and some may wish, in addition, to take postgraduate training or special long term training to qualify for one of the specialties. The Postwar Planning Committee has attempted to anticipate many of these needs, and subcommittees are studying many of the problems preparatory to offering suggestions for their thoughtful solution. This may necessitate the establishment of a clearing house, so to speak, where information concerning these problems will be readily available.

Many state medical associations have already appointed a postwar planning committee to formulate plans for solving of their local problems. As the war advances and as civilian and military medical needs become more acute, there will be greater need for this type of service. To the secretaries of the state societies I wish to direct attention particularly to the needs of the rural population and to request that their needs be studied and a plan of action formulated which will be helpful in supplying them with much needed medical care.

The average graduate of our medical schools today is so well trained that unless clinical laboratory, x-ray, electrocardiographic and hospital facilities for the care of his patients are available to him in a given locality he naturally will seek some other place where these facilities are obtainable. Needs such as this must be considered and solved by each state; the natural organizations to be utilized either in a coordinating or consultative capacity. The location or the relocating of many physicians after the war is over will continue to be one of our chief problems. We, as a profession, can supply the personnel to furnish good medical care, but there are other problems involved in such a procedure in which other groups can be most helpful in supplying facilities.

Finally, I do not come to you with a completed program or with a correct solution for the many problems which will arise in this postwar medical world. I do not know of any one of several methods of procedure which will satisfactorily solve all of these questions, but I do know that we, as a profession, have

devoted and will continue to devote our best efforts to solve our part of this problem. It can best be accomplished through a cooperative effort of county, state and our national medical association and with other agencies interested in postwar problems.

Problems Relating to Assignment of Duties of Military Surgeons

MAJOR GENERAL GEORGE F. LULL, Deputy Surgeon General, United States Army: When the war started we had 1,250 medical officers. If any business expands 100 per cent it is considered that it has had an enormous expansion. We expanded from 1,250 to 40,000. It took place over a period of two or three years. At one time the rapidity of the expansion was enormous. We have discharged, in the last two weeks period, more doctors than we have taken into the Army, so we are not expanding so rapidly now. These men have had to do jobs many of which were similar to the ones they did in civil life, and others altogether different from what they did in civil life. They had to do military medicine. Military medicine is not just putting a uniform on a doctor and putting him to work. Even in a hospital in the interior zone there are certain things he has to do that are different from those he does in civil life. The basic treatment of the sick is the same all over, but there are certain other functions that he has to perform in the Army which are entirely different.

The chief surgical consultant of the British army from North Africa has stated certain principles. "The following points were made in General O'Gilvie's lectures here in this country: 'There are four things that any surgeon, however brilliant and however experienced he may be, must learn afresh when he enters the theater of war: 1. Military surgery is not just traumatic surgery in uniform, but part of the science of warfare. 2. The clinical picture of a wound has to be learned afresh, just like the symptoms and signs of appendicitis. 3. No surgical procedure in war is complete but is a part of a process whose preceding and subsequent steps must be taken into account. 4. The teachings of the last war, which still dominate articles in textbooks, are not applicable today.'" These impressed General O'Gilvie in the practice of surgery in the theater of operations.

When we started to take in physicians who were supplied to us by either the voluntary service system or through the Procurement and Assignment Service, many desired a specific assignment. They wanted to go to Fort X to do x-ray work at Fort X. We told them that we might give them an initial assignment at Fort X to do x-ray work provided there was a vacancy, but after they were originally assigned we had no way of continuing them at Fort X. They would be sent to the place where their services were needed the most, and they would be assigned to do the work that was needed most.

For scarce categories of specialists we have no complaints. We have always been a little behind with the procurement of x-ray specialists; therefore every man who knows anything about x-rays, I believe, is assigned to x-ray work.

There are other specialties for which it is rather difficult to make assignments. Pediatricians, for instance, gynecologists, obstetricians and to a certain extent ophthalmologists and otolaryngologists are difficult to assign.

I believe that this postwar planning which is being sponsored by the American Medical Association is a wonderful project. We should have a plan to take care of these men after they come back from the Army and Navy. However, I believe the problem is not going to be as difficult as we think. A large percentage of these men are going right back to the job and to the place from which they came. As Dr. Paullin has said, the men who have recently graduated in medicine comprise the group we have to take care of particularly. But don't think for a minute that these men aren't learning something in the Army, no matter if they are out with a tactical unit. These men are learning something that they would not learn in a peacetime hospital, nor would they learn it in the practice of medicine until they had been out a long time. Self reliance, working with what they have to work with, having a lot of people dependent on them absolutely for medical care, both the prevention of disease and for the primary institution of treatment, are things they are being taught today.

I talked a short time ago to a man who had just come back from the southwest Pacific. On the particular island we landed at two points. One battalion of infantry landed on a beach, and their objective was to take a certain hill dominated by the Japanese and containing a large number of pillboxes armed with machine guns. The other force was to keep contact with them along the side and come up on the flank of the hill. They became separated in the jungle, and the Japanese on the hill thought that only the small force was coming up the hill, so they left the pillboxes and came down to whip them. That is where they made a mistake. But they did cut our men off from the main body. A shell exploding near a soldier didn't blow his arm off, but it destroyed his forearm, which was crushed and useless; it could not be saved. The young doctor with the battalion had no instruments except a pocket instrument case. He had some ether and some alcohol, so he got his assistant to anesthetize the patient. He put some alcohol in a ration can, lighted it and sterilized a small medical department hand ax. He fixed a frame board and chopped the arm off, covered it with sulfanilamide powder and during the course of the two days gave the patient six transfusions of blood plasma. The man is back in the United States now, he has had his stump repaired, and he is going to live and get along all right. This doctor had been out of an internship only a few months. He went overseas with an affiliated unit as the junior officer in the unit, and he volunteered to go with that party to that island. That boy has learned a lot, and he is only one of many. He has had the courage of his convictions.

We have had letters from your members in which they complain that they have nothing to do. Well, sometimes they have nothing to do because they don't see what they have to do. In the training period in the United States these men are supposed to be training their assistants and their enlisted men to be valuable assistants in time of combat. They have to be ready for the time when combat comes, and this preparation has to be done before they reach the theater of operations.

Many things have to be considered and decided by the senior medical officer with any unit, even if it is a battalion. Where will he establish his battalion and general aid station? Where will he establish it so the soldier will get prompt care and have his life saved? He has to establish that aid station at the nearest possible place back of the line where there is some slight protection and where the soldier can be sent immediately.

The type of warfare they are waging in the Pacific area is altogether different from the type being waged in North Africa. They are two different types of warfare. What the doctor has to do in one place is entirely different from what he does in the other place. The doctor in North Africa, on account of the great mobility of the front lines, might find himself with more German wounded than American wounded, while the American wounded are in the hands of the Germans, because the lines bend back and forth over great stretches of country. It is different in the Southwest Pacific, where the men land on an island where a bulldozer has to make a trail before troops can go ahead, because if they get through the jungle they have no way of bringing up supplies. Climatic conditions are different.

We have one great enemy in both places—malaria. That has been stressed both in the press and in the medical journals, because malaria is something that we must fight just as hard as we have to fight the Japanese or the Germans. It does not kill except a relatively small number of persons, but it does put them out of combat, which is just as important as if they were killed outright.

I think we have a splendid representation of American medicine in the Army. The American soldier as a whole is getting better medical care than he got at home, because many of our boys came from rural areas where the standard of medical care, as Dr. Paullin said, is not the best, because doctors do not like to go to those areas. Our boys are getting a high type of medical care.

One of the first principles is to get the wounded man back to a hospital. In some places this is very difficult to do, and in the Southwest Pacific at times it takes eight litter bearers to carry one man. They have to go in relays over trails and through the jungles. In North Africa sometimes they can be evacuated by airplane direct to a hospital in very short order.

There are a number of things that have cut down our mortality in these advance hospitals. In Tunisia the mortality was between 2.5 and 5 per cent in the advance hospitals. That is a reduction from World War I figures of from 9 to 12 per cent, depending on the action. This is due to a number of things, and it means that if the wounded soldier is taken back promptly his chances of recovery are better than ever before.

I said before that we lost, in the last two weeks, more doctors than we have gained. That is very true. If you read the death notices in *THE JOURNAL* you will see that black box at the end of the death notices. That contains always a number of names of men who died in the military and naval service. A great many of them are killed in airplane accidents. Then we have men who cannot keep up. We took in medical men and lowered the medical standards and waived many disabilities in medical men who were anxious to get into the service. They are being let out now, a few of them at a time, because they simply can't stand the gaff, and each month they amount to a considerable number.

We feel that the medical profession now is divided up in the country about as follows: There are the men in the military and naval services. Second, there are the men who are too old or who are physically disqualified—a large group. Third, there are the men who are essential to civilian life, especially in teaching institutions. Fourth, there is still a group who are nonessential in civil life but who have no desire to enter the military and naval service.

I say this, and I believe I shall be borne out by the Procurement and Assignment Service, which has carefully combed each state for men who are available and who are not available: The voluntary system of recruiting medical officers is over. There are no more volunteers in the United States, except among the group who should not be allowed to volunteer. We will all agree on that. It does not mean that the men who want to come in are all in; there are many men who desire to enter the Army and Navy who should not be allowed to enter because their place is back home. In some places the numbers amount to more than others, relatively and absolutely. But we feel that we are through getting any more volunteers.

We are short many specialists. We have to form a number of hospitals to go overseas, and we are short a great many of the specialists needed to put in those hospitals; that is, the men who have the right training. We can get men who have had partial training, but we feel that the hospitals going out in the next six or eight months will not go out as well equipped, as far as personnel is concerned, as the hospitals that have previously been sent out. This will mean that the theater surgeon may have to make certain adjustments between the hospitals he already has and the ones he is getting, in order to balance the staffs, and it means that all in all the staffs will not be quite as good as they were formerly.

DISCUSSION

DR. HAROLD S. DIEHL, Minneapolis: General Lull, I wish you would comment further on the need of the Army for additional medical officers. From your statement about the stabilization of the medical corps, I think one might conclude that the Army's needs have been met, while, as you know, the Procurement and Assignment Service is receiving exceedingly urgent appeals from both the Army and the Navy for some 12,000 more medical officers.

GENERAL LULL: I did not mean to convey that impression at all. I meant that we were through as far as we were able to get volunteers. The Army needs now, in addition to the men graduating who act as replacements, about 5,000 to 7,000 more doctors. We had a program in which the doctor was placed in a table of organization or an allotment so that it called for about 62,000 medical officers. We saw we could not get them from civil life, that this was impossible. So we tore the table down and felt that if we could get 48,000 or 49,000 doctors we could get along and give the soldier excellent medical care. When we fall below that the care will not be quite as good, but that is something we simply have to make the best of. It means that one doctor will look after a great many more patients. He cannot give them the individual attention that he could give if we had fewer patients, and we can get along with that number, we feel; but we haven't got

that number. I believe the last figures we had showed a rough figure of about 40,000. It isn't because the Procurement and Assignment Service has fallen down on the job of picking them out—it picks them out all right and gives us the names. It turns over to the Office of Procurement Service those names, but then the procedure bogs down. Even when the doctor has signed and mailed his questionnaire, saying he desires to enter the Army first and the Navy second choice, even if he sends that questionnaire in, we have found a good many hundreds of them who absolutely refuse to sign up when the time comes.

DR. STANLEY B. WELD, Hartford, Conn.: Is there any hope that Selective Service will help out the situation at all, especially in the age group between 38 and 45? I believe in our state they are absolutely sitting on their haunches.

GENERAL LULL: I don't know whether they will or not. It all depends on the local board, of course. Some states have cooperated much better than others. When a man refuses to take a commission, his name is sent to the Selective Service. But usually when it gets down to the local board level there is some reason why he should not go into the service; perhaps he is needed in the community.

DR. PETER IRVING, New York: I should like to ask a question as to how the young men who have had only nine months of hospital training have turned out in the eyes of their commanding officers, and whether they have had enough hospital training to make them worth anything?

GENERAL LULL: We haven't enough to know. That is just starting, so we haven't been able to judge it as yet. You know what these men are going to get after the nine months of hospital training: They are not going out with troops right away. Probably half of them will be sent to big hospitals for six weeks, while the other half will go to Carlisle for six weeks of instruction; then they will be exchanged, so they will all get some hospital training.

DR. W. EDWIN BIRD, Wilmington, Del.: Is the Army taking men without state licenses?

GENERAL LULL: Recent graduates, yes. A man who has finished his medical school and his internship is taken without a state license; or if he is a graduate of an accredited school he is taken. We do not take the men who have been out a number of years and who have no state licenses. For instance, we have some cases where a man has been an intern, an assistant resident and a resident for three, four or five years and has never taken a state board examination. We take him if he has been in an accredited hospital.

DR. D. G. EDMUNDS, Salt Lake City: While the Procurement Board has done well, it has not furnished enough men. Do you think the state boards will be done away with and that the government will take over directly?

GENERAL LULL: It is not the fault of the Procurement and Assignment Service that it has not procured the men: it is the fault of the charter under which it operates. It operates under a set of rules whereby it can put the finger on a man, but that is as far as it can go. I do not think they should be done away with.

DR. MORRIS FISHBEIN, Chicago: Can you think of any suggestion that you can give the secretaries and editors as to how they could aid in securing men marked available by the Procurement and Assignment Service?

GENERAL LULL: Public opinion can be brought up locally much better than it can nationally. If there is some way that the finger of public opinion could be pointed toward those individuals it would be a big help to us and to the Procurement and Assignment Service.

DR. R. B. ANDERSON, Fort Worth, Texas: The statement has been made that the Procurement and Assignment Service is helpless in making some of these doctors enter service after they have been declared available. The Procurement and Assignment Service does have a whip and does have a compulsory feature with selective service that can be used for those who are within the age bracket of selective service. I am vice chairman for Procurement and Assignment in Texas. When one of our doctors in Texas is declared available for military service he is informed of it in a letter and is told that

he has been declared available. He is told the proper office of Procurement to which he should go to get his commission. At the same time he is told that we have a directive from the Washington office of Procurement and Assignment that requires our office to report his name to the state director of Selective Service if he does not seek the commission within a certain period. That has been agreed on as reasonable—sixty days. That letter gets results down in Texas.

GENERAL LULL: I think we have got our quota from Texas, too; haven't we?

DR. ANDERSON: We have supplied you with our quota and we have tried to find out how much over we were, because we don't want to fight the whole war.

DR. E. D. SHANKS, Atlanta, Ga.: What happens in Texas is also true in Georgia. Dr. Selman, who is here, is state chairman of Procurement and Assignment. I am a member of that committee. I am also secretary of the Medical Association of Georgia. We have had in our state the usual experiences in procuring doctors for the Army and Navy. We have had, as Dr. Lapham knows, some misunderstanding about some of these doctors. In the end public opinion prevails.

GENERAL LULL: In the smaller communities throughout the country public opinion is so close to the individual that it does have a fine effect. In the big cities the individual doctor is far removed from public opinion.

Hospital Training of Medical Graduates

DR. VICTOR JOHNSON, Secretary of the Council on Medical Education and Hospitals, Chicago: [Dr. Johnson traced the historical development of the Council on Medical Education from 1846 onward.] The permanent Council on Medical Education, established in 1904, reiterated a belief in the indispensability of hospital training. The Council early recognized that internship problems involve features different from those of the hospital training of undergraduates. An important factor is that most hospitals offering internships are removed from the direct influence of medical schools. It became clear that the development of adequate intern training required the Council to obtain better information about hospitals offering intern training. Although in 1913 no medical school or state examining board required the internship for the degree or for licensure (Pennsylvania was the first state to require the internship for licensure [1914] and the University of Minnesota was the first school to require the internship for the M.D. degree [1915]) 70 per cent of the graduates took internships voluntarily at that time. This student recognition of the value of hospital training, supplemented of course by advice from medical schools and physicians, was and still is a more potent factor in inducing students to intern than is regulation through law and degree requirements. At the present time twenty-six states require no internship for licensure, and sixty of the sixty-six four year medical schools do not require this for the M.D. degree. Yet virtually every medical student takes such training.

In approving hospital residencies for training in the specialties, the Council collaborates closely with the various specialty boards. These "American boards," of which there are now sixteen, have been organized by various national societies of specialists in conformity with the Council's Essentials of an Approved Specialty Examining Board. Annual lists of approved residencies, internships and fellowships are prepared. In addition to 1,161 hospitals approved for internships, residencies and fellowships, the Council likewise maintains a hospital register of 6,345 hospitals which, although not approved for internships and residencies, measure up to standards of medical service as set forth in the Council's Essentials of a Registered Hospital. Before considering a hospital for membership, the American College of Surgeons and the American Hospital Association require inclusion of the hospital on the American Medical Association's list of registered hospitals.

Conventionally, the training of the medical student has been divided into three units: two preclinical years, two clinical years and one intern year. A notable trend, extending over many years, has been the erasure of these artificial time delimitations. Clinical material is being introduced into the first years in medical school, vitalizing basic science subject matter

and lending meaning to much that might otherwise seem purely academic. Basic science material is infiltrating itself into the clinical years and increasing their value, with physiology conferences on clinical problems, scientific bacteriology studies on infectious disease patients and the like. Similarly the transition from the senior year of medicine to the internship is becoming less and less abrupt. Through the years there has been a change from clinical work, in which medical students sat in large classes and listened or spent long hours trailing through hospital wards on rounds, to the present system of clinical clerkships, in which the medical student has definite responsibilities as an important member of a hospital team including laboratory technicians, nurses, house staff and attending physicians. The student is on call day and night and often is the first to get the history, make the examination and do the necessary routine laboratory procedures. In some schools selected senior medical students live in the hospital as student interns with responsibilities far beyond those of the medical student of years ago while still subject to close supervision and careful checking.

Wartime acceleration has affected education in all fields of learning and in all stages of the education of a doctor. A serious responsibility rests with every one who has been concerned with the long years of training required for the professions, especially medicine, to evaluate carefully these wartime programs, with a view to retaining after the war those features of acceleration promising to improve our educational program and reduce the training period, consistent with quality.

Of the various accelerated programs, that of the regular undergraduate medical curriculum is perhaps the most likely to justify its permanent retention, perhaps in modified form. The only change is the elimination of the long summer recess. It is not clear why a medical student should be able to do good work for only three fourths of the year and why he requires twelve or more weeks each year away from his job. There is no apparent justification for requiring a student to spend an extra nine months or a year in medical school necessitated by the long vacation periods, which annually waste 5,000 physician years. Immediately on graduation the student will embark on a work program in his internship and residencies in which he will rarely have more than two weeks of respite from work. This will probably continue throughout a lifetime in the practice of medicine. There seems to be no good reason why a student, on graduation, should suddenly cease to require a three months diversion from medicine and abruptly become an individual requiring but two weeks. The accelerated program can allow vacation periods totaling four or five weeks.

I do not propose to discuss all the pros and cons of medical school acceleration except to state that any reduction in educational standards which may have occurred under our wartime program is due far more to several other factors than to acceleration itself. The premedical programs are accelerated not only by employing practically the entire calendar year for instruction but by greatly increasing the quantity of work done by the student per day or week. Whether students can successfully carry this load remains to be determined when the programs have been in full operation for a time. Serious doubts about the quality and breadth of the preparation of premedical students have been expressed. It is highly probable that the degree of acceleration involved in the Army and Navy programs will not and should not be continued after the war. The most recent acceleration—that of reduction of the internship to nine months, with three months in the service considered also as an internship, must clearly be considered a wartime emergency necessity which should be discontinued at the earliest possible moment. This plan, unlike both premedical and medical programs, decreases both the total duration and the quantity of training of a vital part of the education of a doctor.

Adoption of the plan resulted from these important considerations: (1) The periods of overlapping internships caused by the graduation of medical students every nine months instead of annually wasted medical manpower, and (2) the 9-9-9 program was the only method of deferment of commissioned officers as assistant residents and residents that the surgeons general of the Army and Navy would approve. An educational war casualty, the nine months internship has nothing to commend its continuation beyond the emergency period.

It is anomalous that at this time, when our hospitals are impoverished of interns, we must give serious consideration to provisions for a plethora of house officers. This will occur after the war. There will be thousands of medical officers whose hospital training has been interrupted who will seek continuation of their house officerships. Besides providing training for new generations of medical graduates, we are obligated to find opportunities for these medical officers to continue their training.

The Council on Medical Education and Hospitals has undertaken a study of this problem as one of its major responsibilities. In a preliminary survey information has been obtained regarding postwar residencies, basic science instruction, public health education and other postgraduate courses from 641 hospitals, 55 medical schools, 25 departments of health, 23 state medical associations and 15 special societies and examining boards. Information obtained, although incomplete, is most encouraging. Under normal conditions the 660 civilian hospitals approved for residency training supply facilities for approximately 5,500 resident physicians. The present survey reports 8,028 residencies in 545 hospitals. It is apparent that many institutions have almost doubled their educational capacity for postwar training. If this degree of expansion is maintained, it should be possible to develop 12 or 13 thousand residencies in the approved hospitals, especially if the potentialities of the internship hospitals are also taken into consideration.

Just how many medical officers will be seeking advanced training after the war cannot be determined at this stage, for there are still many unknown quantities as regards the duration of hostilities, casualties among medical personnel, rate of demobilization, opportunities for permanent assignment in the Army and Navy, postwar subsidies and other economic factors. It has been estimated, however, that approximately 12,000 graduates of recent years are now serving in the armed forces whose previous training in civilian hospitals did not extend beyond the intern year. Perhaps 6,000 of this group will later seek hospital appointment. In addition there is the possibility that some 2,000 former residents may return to complete their final assignments or establish themselves in other specialties. With a normal civilian complement of 5,500 residents the approved hospitals may also be called on to furnish 8,000 additional residencies in the immediate postwar period.

There is evidence in the reports of the medical schools that careful attention is also being given to the problem of supplying basic medical science instruction in the postwar period. Up to the present time 37 schools have indicated that facilities will be available for continued training in the preclinical fields. Twelve hospitals reported affiliations with medical schools to provide supplementary instruction in basic sciences, while 24 others indicated that courses of this type would be developed in their own departments of bacteriology and pathology. From the information now at hand it is apparent that 117 positions are available in anatomy, 124 in bacteriology, 135 in pathology, 96 in biochemistry and 123 in physiology. Information received from 60 hospitals, 26 medical schools and the various state medical associations and departments of health indicates that 259 postgraduate courses have been organized which can accommodate at least 4,522 physicians. This study will be continued, so that at the close of the war we hope to have available a printed list of all educational opportunities available to returning medical officers and especially planned for them.

DISCUSSION

DR. G. LOMBARD KELLY, Augusta, Ga.: Has any thought been given to increasing the length of the medical course? I have thought it might be possible, after the war, to lengthen the school year to ten months. I see you are in favor of an accelerated program. I do agree with you that three and one-half months is quite a waste of time in the summer. I would like to suggest consideration of a ten months session, four years of ten months each, with July and August omitted. I should like to know what you think of that.

DR. JOHNSON: Your suggestion is an increase in the school year but no reduction in the number of years; in other words, four years of ten months each, with an inclusion of much more into the undergraduate curriculum. I think one could justify increasing the curriculum in terms of total weeks spent in

medical school on the basis of accumulating new information which should be available to medical students, but you can also advance the argument that the medical course ought to be extended for five, six or seven years, using exactly the same arguments, and of course it is a question of just where to draw the line and exactly how much material students ought to get in the medical school, which of course is their beginning of learning about medicine. I would not favor increasing the total weeks in medical school, in laboratories and in lecture rooms. We can greatly increase the effectiveness of the time that is spent in our medical schools by a more careful planning of the content of the curriculum.

SECOND SESSION, FRIDAY AFTERNOON

DR. JOHN S. BOUSLOG, Denver, Presiding

Address of Dr. Herman L. Kretschmer, President-Elect of the American Medical Association

DR. KRETSCHMER: I find in my travels throughout the country a good deal of criticism, a good deal of fault finding, chiefly on the part of men who are not interested in organized medicine and who do not take a very active part. One hears that the American Medical Association does not do anything, that it stands still. I wish to disagree with that statement and to call to your attention just a few things that the American Medical Association has been doing over the past years.

Each day and each week new situations arise that must be met on the spur of the moment. Let me call your attention to the Postwar Planning Committee, the Council on Medical Service and Public Relations and the War Participation Committee. President Paullin this morning told you what his committee is doing and how farsighted it is in its plans for postwar medical service. Through action of the House of Delegates you have established a new Council on Public Relations and Medical Service. Men say to me "Why doesn't that committee do something," being totally unmindful of the fact that you can't appoint a committee by official action of the House of Delegates today and have that committee start to work tomorrow. This committee is represented by men in different fields of practice, from Maine to Florida and from Washington to California. I am sure, with the outstanding men on that committee, that they will be a credit to you and to the American Medical Association; but you will have to give them time to start. There is and has been for some time a drive for a permanent office in Washington and for the establishment of a public relations department in Washington. The public relations technic in medicine is entirely different from that for General Motors, Union Carbide or Bethlehem Steel. I believe the public relations of the Association are being handled perfectly. I have seen at close range this machine work.

It seems to me there is a good deal about public relations technic that we fail to appreciate. I have seen the public relations handled in this organization for a good many years, and I think those of you who may have some doubt in your minds about its workability and its efficiency might do well to discuss some phases of it with the people around this building. I certainly think it would be a mistake to have it run in any other way. I think the headquarters office here watches trends carefully, and the trends, as I said before, change from day to day and from week to week. The Association has been on the alert and has established various committees that are doing a splendid job to meet the situations as they arise.

I should like to say a few words regarding the Board of Trustees. I hear criticism of the Board of Trustees in my meandering through the country. I am not here to toot the horns of the members of the Board of Trustees. You as editors, and you as state secretaries, who have as one of your functions the dissemination of knowledge through your various journals, should be apprised of some of these facts so that when you return to your communities you may correct some of these misconceptions.

I have sat with the Board of Trustees for about twelve years and with the Executive Committee for the same length of time. The Board changes, as you know. Today there is not a single member on that board who was there when I first sat with it

in 1933. The Board has changed completely. Yesterday, as I looked over the Board of Trustees, I was greatly impressed by the fact that there is a general picture of the various types of practice. There are three or four internists on the Board, as rightfully there should be. There are three or four surgeons on the Board, which is fitting and proper. There is an obstetrician and a gynecologist; there is a pathologist, an eye, ear, nose and throat man. There happens to be a urologist. Not only are these men representatives of the various fields of practice but they represent various sections of the country. I am always impressed and always have been with the sincerity with which these men work and the great sacrifices that they make in traveling month in and month out to attend these meetings. They have only one objective. At heart they have the interests of the organized medical profession and the practitioner of medicine. I can assure you they are not a group of nine old men who do nothing but obstruct. They do obstruct when many bizarre proposals come in that are obviously the work of some one with an obsession. Certainly then they obstruct, and that is their function.

I hear little stories going around the country urging that we should have more publicity because we are in bad with the public. I don't believe that statement. At the first meeting of the American Medical Association, practically a hundred years ago, somebody made the statement that they ought to do this or that because he was fearful that the medical profession at that time was in bad with the public.

I ask my patients how they feel about the doctors of medicine. I talk to taxicab drivers, bootblacks, barbers, manicurists and other people. I find little unfavorable criticism of the medical profession. Much of this is nothing but propaganda by self-seeking people. I wish again to emphasize that in my opinion the medical profession stands well with the people in this country; those who say we do not do not know what they are talking about.

I also hear much about the Wagner act. It has had a good deal of publicity. We have all worked hard on it. The combating of the Wagner bill is your job. Each doctor, and this is the message I would like to give you so you may take it back to your constituents, should devote two hours a day to considering this thing and spreading the gospel of what this act means.

The American Medical Association, after all, is your organization. The policies are made by you who elect your representatives in the House of Delegates. Your function, as editors of state journals and secretaries, is to go back and present some of these matters in their right light.

Relationship of Procurement and Assignment Service and State Medical Associations

DR. HAROLD S. DIEHL, Minneapolis, Member Directing Board, Procurement and Assignment Service for Physicians, Dentists and Veterinarians, War Manpower Commission: The Directing Board of the Procurement and Assignment Service has authorized me to express to you, the secretaries of county and state medical societies and the editors of medical journals, its sincere appreciation for the invaluable assistance which you have rendered in the conduct of the work of the Procurement and Assignment Service. Ever since the establishment of this service many of you have devoted a major portion of your time and energy to it. In most states without your cooperation it would have been impossible to do the job and it has become increasingly obvious that the best work has been done where medical societies and Procurement and Assignment Service committees have cooperated most closely and effectively.

When the President of the United States, by executive order, created the Procurement and Assignment Service, he gave to the medical profession of this country the opportunity to itself mobilize, organize and distribute its members in the interests of the war effort. The results would seem to justify this confidence in our profession that we could and would do this effectively.

Medical societies are not expected to, in fact cannot, accept responsibility for the policies or acts of the Procurement and Assignment Service. As an agency of the federal government this service must accept responsibility for its actions. On the

other hand the Procurement and Assignment Service was established on the recommendation of the American Medical Association, and its actions and accomplishments will reflect either credit or discredit on the entire profession. That this has been appreciated is evident from the splendid support which medical societies have given to Procurement and Assignment Service committees. To complete the job still confronting us and to merit future opportunities to handle our own affairs will require the cooperation of every medical society and every member of the profession with the Procurement and Assignment Service. The Directing Board appeals to you for this cooperation.

Foremost among the problems with which we are faced is to aid the Army and the Navy in the recruitment of additional medical officers. The unprecedented number of approximately 50,000 physicians are already in service. Yet our armed forces have reached such a size that the ratio of medical officers to the total strength is only about 60 per cent of that which was considered necessary by responsible authorities to provide adequate medical care in time of war.

All of us hear reports of physicians who are not professionally employed or who are making but little use of their special training and skills. In the mobilization of a vast army and navy some of this is inevitable, but as the tempo of the war is increasing not only will the physicians in service be kept thoroughly busy but many more will be needed to provide for our soldiers the medical care to which each and every one of us would insist they are entitled.

The Procurement and Assignment Service has been alert to underutilization of physicians by the armed forces, but I can assure you that the Directing Board now feels that there is a critical and immediate need on the part of both the Army and the Navy for more medical officers. No one anticipates that it will be possible to procure the number which these services feel that they should have, but the Directing Board does believe that 6,000 or possibly 7,000 more physicians could be withdrawn from certain areas of civilian practice without endangering the health of the civilian population.

To secure this number, physicians must come from all areas in which they can be spared, irrespective of state quotas. Every physician who is not essential where he is must be marked "available" by the Procurement and Assignment Service. And, having thus been released, such physicians must be induced to go into service. At this crucial stage in our war effort no community must be permitted to hoard physicians, and no physicians must be permitted to evade their obligations.

Each of you could cite examples of war industries which have attracted thousands or tens of thousands of workers and their families to areas where little or no medical care has been available, or of medical schools with faculties so depleted that they are unable to maintain the quality of medical education which has become standard in this country, or of hospitals with staffs so reduced that the welfare of the patients is prejudiced, or of civilian communities without that minimum of medical care which is essential for safety. With 50,000 physicians withdrawn from the civilian population and an estimated 6 million people who have moved their homes as a result of the war, some shortages of physicians' services are inevitable. It is the responsibility, however, of the Procurement and Assignment Service and the medical profession to keep these unsatisfactory situations to a minimum. Up to now we believe that this has been done. To maintain as satisfactory a record in the future will be more difficult.

The additional physicians to be released for military service must be most carefully selected. War industries and war boom communities are becoming stabilized, but some of these are still without adequate medical care. Medical schools can release few if any more members of their staffs for military service, and some schools must either have additions to their faculties or reduce the size of their student bodies if a satisfactory quality of instruction is to be maintained. Furthermore, the longer the war continues, the more numerous and acute will become the shortages of physicians remaining for civilian medical care. This is inevitable because the number of graduates of medical schools who will be available each year to enter civilian medical practice is far less than the annual loss of civilian practitioners through death and disability.

Policies and procedures to deal with these situations have been developed and agreed on jointly by the Procurement and Assignment Service, the United States Public Health Service and the War Participation Committee of the American Medical Association. In essence, they provide for the cooperative effort of these groups within each and every state to meet these problems. Such combined efforts were important a year ago; they are imperative today.

Basic to all planning for the remaining duration of the war is complete, accurate and current information concerning the qualifications, location and activity of every physician in the United States. This essential inventory of our medical resources can be made only by the cooperative effort of medical societies and the Procurement and Assignment Service.

We need your assistance also in appraising civilian needs for medical service, in formulating plans to meet these needs and in inducing individual physicians to locate in areas where there are shortages of medical care. We have enough physicians in this country to provide essential medical services during the war for both the military forces and the civilian population if we can distribute them properly and utilize their services effectively. To accomplish such distribution and utilization, however, will require our united as well as our individual efforts.

DISCUSSION

DR. MAXWELL LAPHAM, Executive Officer of the Procurement and Assignment Service: As Dr. Diehl has said, the Army and the Navy do need several thousand more physicians. We have attempted to organize another recruitment program during the past couple of weeks whereby the Army, the Navy and the Public Health Service are meeting with the Procurement and Assignment Service in individual states and going over again the lists of physicians who are declared available for military duty. We have tried this out in Boston and in New York with only a limited degree of success. Unfortunately, many of these men have already been disqualified. Some of them have felt they were disqualified; others feel they are not where they are, and a good many of them are not acceptable to the Army and Navy. As a consequence, only a few hundred of the several thousand will probably be commissioned. However, I think it is worth while continuing this program on a national basis. As soon as we can organize it we will again call on the states to have the officials of the Army and Navy and the U. S. Public Health Service sit in their offices, go over lists of all available physicians again and have consultations with these physicians called into the Procurement and Assignment office so that we can clear up finally all of the men who have been declared available and who have not applied for commissions. Certainly the available men under 38 years of age should be reported to Selective Service if they have not applied for commissions. The Selective Service headquarters tells us that there are a few doctors now who are being inducted, at least in some instances, thereby speeding up the commissioning of men who have been reluctant to apply for commissions before. It has been estimated that possibly 7,000 men are in the available list at present. This does not mean that 7,000 men are physically and professionally accepted for military service. We shall have to deduct the men who are physically and otherwise disqualified.

I would like to mention the new intern resident program. This, we feel, should begin as soon as possible, because many hospitals are in great need of house staffs. Practically all the residents and interns in the hospitals at present are commissioned in the Army and Navy if they are physically qualified. The time would have come shortly when there would have been no residents available for hospital service except those who were physically disqualified, if the Army and Navy had not cooperated in deferring a certain percentage of interns to serve as residents. We realize that there was not an equitable distribution of interns in the United States. Unfortunately there are not enough interns in the United States to fill approved internships; but we have attempted to distribute them as equitably as possible. We have not assigned interns of accredited schools to hospitals that have not been approved by the Council on Medical Education and Hospitals. Many hospitals which in the past had had two year internships took on double the number when the

internship was cut to one year, so if an attempt at distribution had not been made there would have been 500 less interns to distribute in the one year that there had been formerly. We also know that there are about 600 fewer graduates of medical schools who will be available for distribution to civilian hospitals than we had expected this year because the Navy has taken 600 interns into its own hospitals, the Public Health Service has taken 80 into the marine hospitals, so that instead of having 5,200 to distribute we have only about 4,500. As a consequence I can scarcely see how many interns will have to take inferior internships. I would expect that of the 8,000 internships which are approved by the Council on Medical Education and Hospitals approximately half ought to be acceptable to any accrediting agency which might criticize this distribution. Unfortunately, some contracts had to be broken. I have heard, however, from many hospitals, some of which criticized the program most bitterly, that they have been able to send their interns with whom they had contracts to satisfactory internships in other hospitals. I think that within the next few weeks, through the efforts of *THE JOURNAL*, we shall be able to place all of the men who had to seek new internships in hospitals which will be satisfactory to the individual.

The 9-9-9 program for the next nine months, I think, will be much more satisfactory, because with the experience we have had this time in distribution we certainly can improve on it for the October period. With the state committees having a much better insight into the need of local hospitals, their recommendations will be followed as far as possible, so that by the time the schedules are sent out for the next nine months period I think there will be much less difficulty in the distribution of interns and residents to the accredited hospitals in the country.

I might say something about the relocation of physicians. There have been about 2,100 relocations up to the present time in areas where there is said to have been a need. This is a remarkable contribution as far as our state and local committees are concerned, because certainly they have been responsible in large part for this allocation of physicians to the critical areas. We have three groups of people about whom we speak often, and whom we expect to take care of all emergency situations; that is, the physically disqualified practicing physician, the man who is discharged from the Army or the Navy, and the physically disqualified intern and resident. The physically disqualified intern and resident will be used largely, I am afraid, in residencies in the hospitals. We expect some of them, however, to be used for relocation in the critical areas. We should not expect that all physicians who are discharged from the Army and Navy would go back to their homes to practice but that many of them would be interested in going elsewhere. The physically disqualified man who has never been in the service is a very difficult person to move from the place where he is practicing and where he is doing a good job. We therefore have a limited number whom we can select to go to various areas in the country where they are needed. Just recently we have persuaded the Veterans Employment Service of the War Manpower Commission to interview for us physicians who are being discharged from the services, getting information as to whether they want to go back to the place where they did practice before they went into the service, whether they would be willing to go somewhere else, and other pertinent information which will be helpful to us and which we shall send out to our state committees to help them in distributing these men wherever they can be persuaded to go.

DR. R. B. ANDERSON, Fort Worth, Texas: Do residents previously rejected for commissions have to reapply for commissions when you ask for them to be deferred? Does that have to show on the form?

DR. LAPHAM: If they have been disqualified by the Army since August 1942 they do not have to reapply for a commission. If any one had been disqualified before that time he was supposed to have applied for a commission again, because the standards had been lowered since that time.

DR. ANDERSON: When making a request for the deferment of a resident, if he has been previously disqualified for a commission within the past year all we have to do is to so state on the form?

DR. LAPHAM: You do not have to ask for the deferment of a man who has been disqualified by the Army because he does not hold a commission.

DR. ANDERSON: At what time before the expiration of an internship should appeal for deferment for a residency be made?

DR. LAPHAM: It should be made as soon as the man is appointed to the residency. In other words, if you want to start next week requesting us to ask for the deferment of a man who is now serving a junior residency and who is a commissioned officer, to serve as a senior resident beginning next October, you may do it. I would prefer that you wait until possibly the first of March or April, until we can reappraise all the hospitals, so that the state chairman will have in their offices the quotas which are established. If, however, there are instances in which a hospital wishes to know definitely whether it can employ a certain person because he is planning to go to some other hospital, then I think you may ask for the deferment of that man right away for the period beginning October 1.

DR. ANDERSON: If an intern, man or woman, refuses to apply for a commission, is there any use asking for deferment of that physician for residency?

DR. LAPHAM: There is no point in asking for his deferment anyway, if he is not a commissioned officer, as long as you stay within the quota established for that hospital. You have only to ask for deferment on those people who are commissioned either in the Army, the Navy or the Public Health Service, but you should insist on every physically qualified noncommissioned intern or resident applying for a commission.

DR. W. S. LEATHERS, Nashville, Tenn.: I should like to ask a question with regard to the assistant resident who has been deferred until July 1. If that man goes July 1 we shall fail to have our quota between July 1 and October 1. What can we do about that?

DR. LAPHAM: Those men who were commissioned recently and who were deferred for a complete year of residency were deferred largely until July 1. We discussed this problem with the Surgeons General of the Army and the Navy and tried to get them to say that they would defer all of those men to October 1, which would make the program balance and would not leave a gap in house staffs from July to October. They were not willing to do that at this time, but I believe that between now and the first of May we shall be able to work out with the Surgeons General of the Army and the Navy some plan by which some of those men will be deferred until October 1. We felt that we had gotten over one big hurdle when we were able to get a certain number of those men deferred for the nine month period.

DR. T. M. DYE, Clarksdale, Miss.: What is the chance of getting a commission for a man who is physically fit and a little over 45 years of age? In my state, Mississippi, in the beginning of the Procurement and Assignment Service the survey showed that there were only 350 available doctors. Out of those 350 doctors we have already commissioned 300. We have a few men who were in the first world war, over 45 years of age, who would like to get a commission.

DR. LAPHAM: The Army and Navy both, of course, will take men up to and beyond age 45, but they have felt from experience that they would prefer to have the men under 38, particularly, but certainly, generally speaking, only men up to 45. They can use them in practically any field, and the older men they feel they cannot. At the present time in the Army and the Navy there are about 2,900 physicians over 45 years of age. Many of them, of course, are members of the regular army or navy medical corps. However, if the man over 45 has special qualifications which will make him unusually useful to the Army and Navy, they will accept him, and they are quite willing to accept the applications of those men.

DR. RANKIN C. BLOUNT, Louisville, Ky.: I hope that Dr. Lapham will recall that chairmen have been called on to clear for review a great many cases of men who have been rejected for physical reasons. Some of us have the impression that for standards have been lowered. However, in my state I have cleared many men for review. I can recall only three who were qualified after examination. Many of the men who have been

cleared for review have been put to a great deal of expense of time and have come in with conditions for which they were rejected formerly, and the examination station was told that there should have been no reason for them to come in. For instance, two had heart disease and hernia, and any number of them had arthritis. The first of this week I had the Army procurement officer come to my office with over forty names. I went over my records carefully with him to show cause for rejection. Among that list were three who had been rejected and who had held reserve commissions, who were over 50 years of age. Among that list were seven who had been released from the Army, and it was suggested that we review them. When I got through with the list the procurement officer agreed with me that there certainly was not more than a possibility of three men passing a physical examination again. I didn't mind the time it took to go over the list; it took practically half a day for him and me to clear all of those records, but I am wondering by what process the Army procurement officers are getting some of these names for review and reexamination, whereas on the very face of the records it would seem that unless standards are considerably lowered there would not be a chance of their passing again.

DR. LAPHAM: I am glad you brought that question up, because the Procurement and Assignment Service felt strongly about recommending to the Surgeon General the lowering of physical standards, particularly because we have heard from our state offices, from medical groups, that there were lots of doctors who had been turned down by the Army, who to all intents and purposes were doing a big job at home. Their physical qualifications did not prevent them from carrying a heavy load. In order to get as many doctors as possible for the Army and Navy, we said we would be glad to clear any physically disqualified men they wished to reconsider. The reason we insisted on clearance a second time was that a great many of them have been put in essential positions and we want to be sure that these particular ones were still available for military service. As far as I know, the Surgeon General's Office has gone over that list and has indicated the names of men who they thought might pass a second physical examination. I am sure in some instances they have been wrong. Somewhere between 20 and 30 per cent of these men, whose names have been sent to us for clearance a second time, are now qualified for commissions. So possibly it has been worth while. I think the Army has sent us the names of some 1,800 or 2,000 physicians. We have cleared at the present time something like 1,200 or 1,400, and we hope we can get a few out of the remaining number.

The War Participation Committee as a Coordinating Agency

DR. WALTER F. DONALDSON, Pittsburgh, Chairman of the War Participation Committee of the American Medical Association: War Participation committees do have a function. If you have enough faith that your committee may render a service, you are going to find opportunities to give advice, and that is what a lot of us love to do. When I write to you as chairman of the Association's Committee on War Participation regarding a similar committee in your state, you reply to me "That work is being done by our Committee on Procurement and Assignment." Now, gentlemen, the Committee on Procurement and Assignment in any state medical association has certainly had enough to do in the last two years not to be looking for extra duties. Many of them served a year preceding that appointment as members of a Committee on Medical Preparedness. Undoubtedly their thinking in these directions is pretty well consolidated, and they are not likely to be enthusiastic when our committee or somebody else writes and asks them to get outside of that field.

Our committee has found opportunities to coordinate. Since the last meeting of the House of Delegates we have been called to Washington twice by the directing board of Procurement and Assignment. They had problems which they thought we could help them solve, and we were pleased to respond. I am sure in some instances we did help with the solution of these problems. We accomplished more in that solution in the states where there is a separate Committee on War Participation than we did in the states where there is no committee with

that specific title. I realize that you as secretaries and editors cannot authorize or create such committees, but I would appeal to you to put the pressure on your board of trustees or your council, or whatever you might call that important group, to authorize the creation as soon as possible of a Committee on War Participation; then, at the next meeting of your state association, have that confirmed by your house of delegates. In a number of states the Committee on War Participation can do a tremendous amount of leg work for Procurement and Assignment. As you have heard their difficulties described here today, I think you should be willing to agree that it would not do that situation harm in many states if some new faces entered into the various communities where there are men who need to be smoked out to apply for a commission. It is not only in the large cities that men who should be commissioned are in hiding. There is many a town and city in the United States with a population anywhere from 10,000 to 25,000 that has two or three doctors who might well be spared.

A Committee on War Participation might very well interest itself in the maintenance of war records of their fellow members absent in the service. There is no finer contribution that a county medical society could make to win the affection of a

young man. Let him learn either while he is in service or when he comes back that his fellow practitioners on the home front have interested themselves in recording his commission, his service and everything else that goes with that sort of a record. I believe—and other members of my committee believe—that the doctors who are in the service under 35 years of age are going to expect change in the local medical situation when they return to private practice. National committees may readily plan opportunities for graduate study to be available to all returning physicians, and doubtless openings for returning practitioners will be carefully assembled on a national scale for the choice of the unsettled physician. But what of the military doctor who has ideas not yet crystallized in his own mind or whose chief immediate worry anent his return is economic? Who can anticipate the needs that may be amenable to constructive aid or solution better than his fellow practitioners remaining on the home front? How better obtain the answers to such questions than by addressing them to your members before they come home. The responsibility of formulating plans to assist state medical society members returned or returning from military service may well be assigned to your war participation committee.

(To be continued)

WOMAN'S AUXILIARY

Colorado

The Woman's Auxiliary to the Colorado State Medical Society recently issued its yearbook, which has been dedicated "to the Doctor." It contains the report of the Philanthropic and Benevolent Fund, which shows on Sept. 1, 1943 a balance of \$5,364.29. The trophy, a silver bowl, goes to Pueblo County for having made the largest per capita contribution to the Emergency Fund. Mrs. Laurence T. Brown of Denver is president.

Georgia

A booklet containing the program for the year's work of the Georgia auxiliary has been compiled by the president, Mrs. Olin S. Cofer of Atlanta. The general theme is "Health for Defense." The auxiliary will stress education on proper nutrition and education about tuberculosis, cancer and venereal disease.

Indiana

The annual convention of the Indiana auxiliary was held in Indianapolis recently, with an attendance of 300. Mrs. James W. Baxter Jr. is the new president. Mrs. Rollo K. Packard, one of the speakers, urged the members to fight the Wagner-Murray-Dingell bill, saying "Since there are more women than men to vote in the next election, what greater opportunity could we have?"

Allen County has two projects for the year—the sponsorship of occupational therapy for the patients of the Irene Byron Sanitarium and the collection of costume jewelry for service men stationed in the Pacific Islands.

Members of the Floyd County auxiliary assisted the Floyd County Medical Society and the Third District Health Department in the annual immunization program.

Michigan

The seventeenth annual meeting of the Woman's Auxiliary to the Michigan State Medical Society was held in Detroit recently. There were 63 delegates and 43 guests registered. Mrs. J. J. Walch is president for 1943-1944. Mrs. Eben J. Carey, national president, spoke of the growth of the auxiliary and explained the Nurses Cadet Corps project.

Ohio

The Belmont auxiliary and medical society contributed sufficient funds to care for a Chinese orphan for a year.

Lucas County auxiliary had a luncheon meeting in October at the Toledo Women's Club, and a panel discussion on "Juvenile Delinquency in Lucas County" was held.

The new project of the Ross County auxiliary, which has made dresser covers and tray cloths for the hospital and done

much Red Cross sewing, is the making of surgical bandages from material reclaimed from recapped tires. Members wash material at home and return it cleaned and pressed to the Red Cross rooms.

Cuyahoga's special project is knitting for the Red Cross. Since the beginning of the project 768 articles have been completed.

Oklahoma

A recent issue of the *Journal of the Oklahoma State Medical Association* contains an article by Mrs. F. Maxey Cooper, president of the Oklahoma auxiliary, in which she writes "The year ahead bring us a threefold challenge: (1) We must meet immediate war needs, (2) we must carry on as normally as the time will permit, (3) we must plan for peace and a better world of the future."

Pennsylvania

The Pennsylvania auxiliary will assist in obtaining complete war records of the physicians in service. At the fifteenth annual meeting of the second councilor district of Pennsylvania, held at Reading recently, the auxiliary membership in the district was 541, and \$1,175 was given to the Medical Benevolence Fund.

Berks County auxiliary, at a meeting held recently in Reading, voted to pay for the duration all dues, state and benevolence, of all wives in the auxiliary whose husbands are in the service.

Cambria, Erie, Franklin and Lycomings auxiliaries report good meetings. The latter auxiliary purchased three \$100 war bonds during the third war loan drive.

The Woman's Auxiliary to the Beaver County Medical Society met at the Penn Beaver Hotel, Rochester, Pa., November 23. Thirty-two members were present. Mrs. A. W. Cully, president, conducted a short business meeting. Mrs. J. L. Whitehill gave a report on the Wagner-Murray-Dingell bill and the activities of the recent state convention at Philadelphia. Mrs. J. A. Stevens, Aliquippa, was appointed chairman of the War Participation Committee. The annual benevolences of the auxiliary were (1) \$50 to the Passavant Hospital, (2) \$50 to the Beaver County Tuberculosis Sanitarium, (3) a \$10 T. B. bond and (4) \$5 to the Salvation Army. The speaker was Dr. J. A. Mitchell, who spoke on industrial medicine.

Mrs. Walter Orthner, president of the Pennsylvania auxiliary, said in her address that, "While we, the United Nations, are fighting this great conflict for the four freedoms, we on the home front must continue to fight for the fifth freedom, namely freedom of individual enterprise. If we allow ourselves to become regimented or bureaucratically dominated, we only follow in the footsteps of those dictator nations against which we are battling."

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Physicians Needed.—The department of civil service and personnel of San Diego County announces that the positions of superintendent of the San Diego County General Hospital and assistant director of county public health are available. The former position will pay between \$490 and \$586 a month and the latter \$349 to \$364. Additional information can be obtained from the department of civil service and personnel, Room 212, Civic Center Building, San Diego 1.—The Los Angeles County Civil Service Commission announces openings for positions as resident physician (urology) in the Los Angeles County Hospital and other county institutions, the applications to be filed on or before January 20. Further details can be obtained from the office of the commission, 102 Hall of Records, Los Angeles 12.

CONNECTICUT

Liberty Ship Named for Harvey Cushing.—A liberty ship named in honor of the late Dr. Harvey Cushing, New Haven (SS 1896), was recently launched at the St. John's Shipyard in Jacksonville, Fla. A U. S. Army Hospital at Framingham, Mass., is also to be named in honor of Dr. Cushing and will be known as the Cushing General Hospital. During World War I Dr. Cushing organized base hospital number 5, the Harvard Medical School and Peter Bent Brigham Hospital unit. The buildings of the new hospital are completed and the hospital is staffed, according to the *News* of the Massachusetts General Hospital. The late Dr. Cushing held the rank of colonel and received the Distinguished Service Medal for his service during World War I.

Medical Students Awarded Prizes.—At the graduation exercises of Yale University School of Medicine, New Haven, December 18, the Ferris Prize in anatomy, given for excellent work in dissection, was divided among three students: Thomas A. Doe, Linden, N. J., James A. Kleeman, Springfield, Ohio, and William J. Wedemeyer Jr., Upper Montclair, N. J. The Campbell gold medal, awarded to the graduating student who secures the highest rank in the examinations of the course, was given to Dr. Donald W. Seldin, Brooklyn, honorable mention went to Dr. William K. Welch, Lebanon, Pa. The Keese Prize, awarded to the student who presents the best thesis was given to Dr. Charles W. Watson, Tulsa, Okla., with honorable mention to Dr. John J. Milford, Huntsville, Ala. Dr. James L. Bradley, Lyons, N. Y., received the Parker Prize given to the graduating student who has shown during his course the best qualifications for the successful practitioner. The Ramsey Memorial Scholarship, awarded to the student of unquestioned ability and character after completing his first year in clinical medicine, was given to Robert E. Cooke, Windsor, Conn., and the Mendel Prize in physiologic chemistry went to Edward F. Edinger Jr., Bedford, Ind. Forty-nine students received the degree of doctor of medicine, of whom Dr. Bradley, Dr. Ira A. Rashkoff, New York, Dr. Ellen F. Regan, Framingham, Mass., Dr. Seldin, Dr. Welch and Dr. James T. Wolstenholme, Clifton, N. J., were graduated cum laude.

FLORIDA

State Medical Meeting to Be in St. Petersburg.—The seventy-first annual meeting of the Florida Medical Association will be held in St. Petersburg, April 13-14.

Physicians' Committee Appointed for Fee Schedule.—A special committee was recently created to represent the Florida Medical Association when called on by the Florida Industrial Commission (workmen's compensation division) in matters relating to a fee schedule. Members are Drs. Ferdinand A. Vogt, Miami, chairman, Alfred M. Bidwell, Tampa, Frank L. Fort, Jacksonville, Lloyd J. Netto, West Palm Beach, Eugene G. Peek, Ocala, and Wilfred McL. Shaw, Jacksonville.

Personal.—Dr. James Maxey Dell was recently selected mayor commissioner of Gainesville. Dr. Dell, who is beginning his ninth year as a member of the commission, served as mayor commissioner in 1938-1939.—Dr. George N. MacDonell,

former health officer of Miami, has been appointed chief of the medical service division of the Dade County Defense Council. Dr. MacDonell succeeds Dr. Gerard Raap, Miami, who recently resigned because of ill health.—Dr. Charles L. Clay, Miami, has resigned as medical superintendent of the James M. Jackson Memorial Hospital, effective November 1. The state medical journal reported that the hospital would be reorganized into two divisions with a medical director and a business administrator.

ILLINOIS

Investigate Sale of Vitamins.—Charges that the state of Illinois had paid thousands of dollars for inferior and useless vitamin pills sold to twelve mental hospitals were to be investigated by federal authorities, newspapers reported, December 16. It was stated that the food and drug administration had requested the state department of public welfare to prepare a report on alleged sales involving hospitals at Alton, Anna, Dixon, Elgin, Moline, Menard, Kankakee, Manteno, Jacksonville, Peoria, Lincoln and Chicago. Payment on a \$60,000 contract was ordered stopped until contents of the latest shipment were tested, it was stated. Public welfare officials were reported to have complained that the pills were below specifications and that previous shipments had been received in defective and unusable conditions. The newspaper reports stated that the vitamin sales, exclusive of the \$60,000 order, totaled about \$75,000. The reports stated that one recent shipment was rejected because it contained "just bottles full of oil" resulting from bad packing, and that another shipment contained only 25 per cent of the vitamin quantity desired.

Chicago

Annual Election of Institute of Medicine.—Dr. Ludvig Hektoen was again chosen honorary chairman of the board of governors of the Institute of Medicine of Chicago at a recent meeting. Dr. William F. Petersen was again named chairman and Dr. Andrew C. Ivy was chosen president. Other officers are Drs. Harry S. Gradle, vice president, George H. Coleman, secretary and Grant H. Laing, treasurer. The newly elected members of the board of governors for terms of given years each are Drs. Bowman C. Crowell, Herman L. Kretschmer and Eric Oldberg.

Meeting of Psychotherapy Council.—The second annual meeting of the Brief Psychotherapy Council will be held at the Ambassador Hotel, January 14-16, under the auspices of the Chicago Institute for Psychoanalysis. The first day will be given over to a discussion of "War Psychiatry" and the second to "Therapeutic Aspects of Psychosomatic Medicine." The third day will be divided between "Psychotherapy for Children" and "Group Psychotherapy." Included among the speakers will be:

- Lieut. Col. John M. Murray, M. C., A. U. S., Some Special Aspects of Psychotherapy in the Army Air Forces
- Dr. Alvan L. Barach, New York, Impairment in Emotional Control Produced Both by Lowering and by Raising the Oxygen Pressure in the Atmosphere, with Observations on Normal Young Men Exposed to an Altitude of 15,000 Feet
- Lieut. Col. Roy R. Grinker, M. C., A. U. S., Use of Brief Psychotherapy in War Neuroses
- Molly R. Harrower-Erickson, Ph.D., Montreal, The Use of the Multiple Choice Test in the Military Services
- Samuel J. Beck, Ph.D., Rorschach's Test in Men Discharged from the Military Services
- Frederic L. Wells, Ph.D., Boston, Notes on the Recognition of the Psychologically Marginal Recruit
- Dr. Bela Mittelman, New York, The Cornell Selectee Index: A Method for Quick Testing of Selectees for the Armed Forces
- Major Milton L. Miller, M. C., A. U. S., Brief Psychotherapy in a Preflight Training Center of the Air Corps
- Capt. Carel von der Heide, M. C., A. U. S., Psychiatric Observations in Two Station Hospitals
- Dr. Edward Weiss, Gastrointestinal Disturbances
- Dr. George E. Daniels, New York, Diabetes
- Dr. Thomas M. French, Asthma
- Dr. Helen Flanders Dunbar, New York, Rheumatic Disease, with Special Reference to Psychosomatic Diagnosis and Treatment
- Dr. Franz G. Alexander, Psychologic Approach to Hypoglycemic Fatigue
- Dr. Irving Edward Liss, New York, Sadosmochism in a Case of Thrombocytopenic Purpura Hemorrhagica
- Dr. Editha Sterba, Grosse Pointe Park, Mich., Brief Psychotherapy with Orthopedic Cases
- Dr. Marian C. Putnam, Boston, Psychotherapy in a Guidance Center for Infants and Preschool Children
- Dr. Emmy Sylvestre, Chicago, Emergency Treatment of Severe Feeble-minded Disturbances
- Fritz Redl, Ph.D., Detroit, Problems in Clinical Group Work with Children
- Kurt Lewin, Ph.D., Iowa City, Experiments on Rapid Changes in Industry
- Dr. Jacob L. Moreno, New York, A Case of Paranoia Treated Through Psychodrama

LOUISIANA

Dr. Pinto Resigns as Director of Industrial Hygiene.—Dr. Sherman S. Pinto, New Orleans, supervisor of the section of industrial hygiene of the Louisiana State Board of Health, has resigned to accept a commission in the medical corps of the U. S. Army. W. H. Reinhart, engineer in the section, is acting director.

MISSISSIPPI

License Revoked.—The state board of health, acting as a legal court of inquiry, on October 21 revoked the license of Dr. Benjamin F. Johnson II, Jackson, after he was found guilty of "procuring an abortion or abortions that were not necessary to preserve the life of pregnant women."

Personal.—Dr. Harvey F. Garrison, Jackson, has been appointed a member of the advisory committee to the U. S. Children's Bureau, Department of Labor, Washington, D. C. —Dr. Cyrus M. Shipp, Bay St. Louis, director of the Hancock County Health Department, was recently chosen president-elect of the Mississippi Public Health Association and Dr. John B. Grant, McComb, was installed as president.

MISSOURI

State Cannot Restore License to Muench Without Examination.—Attorney General Roy McKittrick informed the state board of health in an opinion November 30 that it does not have authority to consider the application of Dr. Ludwig O. Muench, St. Louis, for restoration of his medical license, but that it might pass on an application for an examination and issuance of a new license, according to the *St. Louis Globe-Democrat*. Dr. Muench was released on June 6 from the federal prison at Terre Haute, Ind., having served six years on a conviction of using the mails to defraud, newspapers reported (*THE JOURNAL*, July 31, 1943, p. 959). He was found guilty in 1935 of unlawfully and fraudulently making out, signing and certifying a fraudulent birth certificate. In 1937 his license to practice medicine was revoked by the state board of health for unprofessional and dishonorable conduct. An application for restoration of the license was filed in September, the *Globe-Democrat* reported. It was stated that the attorney general's opinion held that the action of the state board, taken March 10, 1937, revoked Dr. Muench's license permanently and pointed out that there is nothing to prevent the physician from filing application for a new license and that the state board would have authority to consider such an application, subject to present laws and rules and regulations.

NEBRASKA

Newspaper Finances Children's Hospital.—The *World-Herald* has given \$100,000 toward the construction of a children's hospital in Omaha to be called the Children's Memorial Hospital and to be erected on ground leased from the University of Nebraska College of Medicine. In addition, stockholders of the *World-Herald* have contributed \$15,000 toward the project. The hospital will be entirely independent of the university and not a state institution. A 50 bed unit, expected to cost at least \$200,000, will be constructed first. The remainder of this cost above the contribution of \$115,000 will be raised by public subscription. According to the *World-Herald* complete development of the plan calls for a 150 bed hospital, and additions to reach this size, it is hoped, will be financed by later donations and bequests. The hospital will be operated by a nonprofit corporation of which A. A. Lowman, W. Dale Clark, Ben H. Cowdery, David Goldman, C. Louis Meyer and Linn P. Campbell, all of Omaha, were the incorporators. Mr. Lowman is president, Mr. Campbell, vice president, Mr. Cowdery secretary and Alvin E. Johnson, Omaha, treasurer. The \$115,000 donation carried no stipulation but recommended to the trustees that about 40 per cent of the beds be maintained for children whose parents are unable to pay and that these beds be free to child residents of Nebraska and western Iowa and "that the hospital be kept under private management of a board of trustees solely for the benefit of our community, and that it be entirely undenominational and open to the public generally and that the medical staff be picked impartially from all the doctors in the city." It was stated that the American Academy of Pediatrics would be enlisted in the formation of the staff. The hospital will be located on a site somewhat larger than a city block between 44th and 45th

streets and Dewey Avenue and Jackson Street. The *World-Herald* in announcing the gift pointed out that there is not a children's hospital in Nebraska. An attempt will be made to obtain priorities so that plans for the new project may go forward as soon as possible.

NEW YORK

Chief Resident Wins Clough Prize.—Dr. Andrew Kerr Jr., chief resident physician at the Rochester General Hospital, Rochester, on December 17 was named the first recipient of the Harry D. Clough Memorial Prize. The award, which is limited to house officers, is conferred on the basis of excellence of conference case presentations and general support of the weekly clinical conference at the hospital. Its establishment was announced October 22, and the award consists of the \$25 cash prize and the inscription of the recipient's name on a special plaque in the conference room. The prize is a memorial to Dr. Clough, assistant medical director of the hospital, who died Oct. 1, 1942 and who worked for the development and improvement of the hospital conferences (*THE JOURNAL*, Nov. 27, 1943, p. 850).

New York City

Fourth Harvey Lecture.—Karl Paul Link, Ph.D., professor of biochemistry, University of Wisconsin, Madison, Wis., will deliver the fourth Harvey Society Lecture of the current series at the New York Academy of Medicine on January 20. His subject will be "The Anticoagulant from Spoiled Sweet Clover Hay."

Lectures to the Laity.—A group of lectures to the public will open January 14 at the Brooklyn Academy of Music with a talk by Col. Charles M. Walson, M. C., U. S. Army, on "Progress of Medicine in War." Others in the series will include Dr. Benjamin W. Carey, Pearl River, N. Y., "Germs and Germ Fighters," January 21; William M. Malisoff, Ph.D., "The Chemist Looks at Medicine," January 28, and Dr. Louis H. Bauer, Hempstead, L. I., "Medicine Takes to the Air," February 4. The lectures will be sponsored by the Brooklyn Institute of Arts and Sciences, the Medical Society of the County of Kings and the Academy of Medicine of Brooklyn.

Medical and Health Organizations Cooperate in Health Broadcasts.—Public health and medical societies in New York City cooperate with the city's own station WNYC in the program of health talks designed to safeguard and preserve the people's health. According to a release, more than 60 per cent of all health talks heard over New York stations are broadcast over WNYC. On Mondays and Fridays the speaker for the "New York City Health Time" is provided by the New York Academy of Medicine in cooperation with the New York Tuberculosis and Health Association. The Oral Hygiene Committee of Greater New York offers advice on dental matters by prominent members of the dental profession on Tuesdays. Dr. Jerome S. Peterson of the New York City Department of Health gives the Wednesday talks, on community health problems. Thursday morning's speaker is from the Medical Society of the County of New York, and the alternate Saturday discussions are sponsored by the Bronx County Medical Society in cooperation with the Bronx County Tuberculosis and Health Association and the Medical Society of the County of Kings.

Right of Physicians to Prescribe Heavy Cream May Be Withdrawn.—On December 22 the Milk Industry Advisory Committee recommended that the War Food Administration consider withdrawing the right of physicians to prescribe heavy cream for their patients, at present the sole exemption to the nationwide ban on the sale of whipping cream, the *New York Times* reports. The recommendation carried the suggestion that the privilege had been abused and listed a number of specific instances of "alleged abuses" of the right to prescribe heavy cream. The *Times* reported that "one involved the prescription by a physician of heavy whipping cream for seventeen persons in his own family." Many other cases were noted in which the prescribing physician directed his patient to dilute the heavy cream with milk. The *Times* states that all the medical societies in the New York area were informed of the purpose of the meeting at which the action took place and invited to participate in the discussion. None were represented. Public health agencies in the district did attend and advised the committee that the exemption in favor of prescription sales should be reviewed. It was stated that the prescrip-

tion sales created special sanitary problems for handlers, since the mechanized volume production methods used in packaging 19 per cent (light) cream could not be employed and that the system creates a large body of preferred consumers. Quoting a report, it was stated, "Inasmuch as the committee has reviewed opinions that would indicate that heavy cream, in ordinary prescriptive use, has little or no therapeutic or dietetic value superior to cream of lesser butterfat content, the committee is of the opinion that the exemption should be reviewed and probably withdrawn. Among the practices that indicate the wisdom of a review are the common instructions to patients to dilute the heavy cream after buying it and the frequent failure of physicians to prescribe a cream of specific butterfat content. These practices along with specific opinions that the prescription privilege has been outrightly abused are cited in a stenographic record of the committee's last meeting."

PENNSYLVANIA

License Suspended.—The license of Dr. Walter J. Rogan, Dushore, and formerly of Bridgeport, has been suspended because of his violation of that section of the medical practice act which pertains to "habitual intemperance in the use of ardent spirits or stimulants, narcotics, or any other substance . . . which impairs intellect and judgment to such an extent as to incapacitate for the performance of professional duties."

Philadelphia

University News.—A urologic room has been added to the surgical suite of the Hospital of the Woman's Medical College of Pennsylvania through the generosity of Mr. William Goldman. It is outfitted with modern surgical and x-ray equipment for both diagnostic and therapeutic procedures and for teaching and is under the supervision of the department of urology. The department of medicine is conducting a weekly series of postgraduate lectures. First year students are attending a special course of lectures in medical statistics given by Mr. G. St. J. Perrott, chief, division of public health methods, and Antonio Ciocci, S.D., U. S. Public Health Service. Richard H. Shryrock, Ph.D., professor of the history of medicine, University of Pennsylvania School of Medicine, who has been made special lecturer in medical history at the Woman's Medical College, is giving a series of weekly lectures on interpretation of medical history.

Goddard Memorial Lectures on Legal Medicine.—The Philadelphia County Medical Society has named its annual series of lectures on legal medicine the "Dr. Herbert M. Goddard Memorial Lectures on Legal Medicine" in honor of Dr. Goddard, who at the time of his death on Nov. 23, 1943 was assistant director of public health of Philadelphia and county coroner. The second series of lectures, which were inaugurated last year, opened on January 7 with a talk by Chief Justice George W. Maxey on "Legal Aspects of Medical Practice." Subsequent lectures will include:

- Judge Charles Kenworthy, Unprofessional Conduct. Malpractice, January 14.
- John D. Maurer, district attorney of Philadelphia County, and John A. Boyle, first assistant district attorney, Joint Functions of Prosecutor and Coroner, January 21.
- John F. Sears of Federal Bureau of Investigation, Scientific Crime Detection, January 28.
- Dr. Thomas A. Gonzales, medical examiner of New York City, The Medicolegal Autopsy, February 4.
- Dr. Alan R. Moritz, professor of legal medicine, Harvard Medical School, Boston, Special Evidentiary Objectives of Medicolegal Post-mortem Investigations, February 11.
- Dr. John H. Foulger, director of Haskell Laboratory of Industrial Toxicology, Wilmington, Del., Occupational Hazards and Diseases, February 18.
- Irvin Bendiner Esq., Medical Insurance, February 25.
- Dr. Edward A. Strecker, professor of psychiatry, University of Pennsylvania School of Medicine, Psychiatry and Law, March 4.
- J. W. Holloway Jr., director of the Bureau of Legal Medicine and Legislation, American Medical Association, Chicago, Legal Medicine and the Professions, March 11.

TEXAS

Physicians' Art Work.—Through the courtesy of Mead Johnson & Company, Evansville, Ind., an exhibition of physicians' art work was held in the Rosenberg Library, Galveston, recently. The collection was the work of members of the American Physicians Art Association and included a few pieces from Texas physicians.

Hospital News.—The new Orange City-County Hospital, erected with federal funds at a cost of about \$275,000, was recently opened. The one story building has a capacity of 76 beds. Members of the Orange County Medical Society and

the Sabine District Medical Society constitute the charter members of the staff. Dr. Thomas E. Kelly, Mount Pleasant, is chief of staff and Dr. Stanley M. Richmond, Marshall, secretary.

UTAH

Personal.—Dr. Donald J. Bourg, Corvallis, Oregon, has been lent to the state of Utah to serve as director of the first councilor district with headquarters at Ogden, succeeding Dr. William P. Scarlett. The district comprises the counties of Weber, Box Elder, Cache, Rich, Morgan and Summit.—Dr. Paul K. Edmunds, Van Nuys, Calif., has been appointed health officer of district number four of the state department of health with headquarters in Provo.

VERMONT

Changes in the Faculty.—Ferdinand J. M. Sichel, Ph.D., has been promoted to associate professor of physiology at the University of Vermont College of Medicine, Burlington. James E. P. Toman, Ph.D., instructor in physiology, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, has been named instructor in pharmacology and physiology at Vermont, and Miss Nancy Hart has been named research assistant in the same department.

GENERAL

Ashford Award Goes to Norman Topping.—The Bailey K. Ashford Award was presented to Norman H. Topping, P. A. Surg., U. S. Public Health Service, National Institute of Health, Bethesda, Md., for outstanding work in the field of tropical medicine. The presentation was made during the annual meeting of the American Society of Tropical Medicine in Cincinnati in November. In 1941 Dr. Topping went to La Paz, Bolivia, to study the effects of a typhus vaccine developed at the Rocky Mountain laboratory of the U. S. Public Health Service, Hamilton, Mont. He is a member of the United States of America Typhus Commission.

Award for Research in Human Fertility.—The Planned Parenthood Federation of America announces an award of \$500 to be given in 1944 to the scientist who has made the most significant contribution to research in human fertility, either in the control of conception or in the correction of sterility. Any scientist anywhere in the world will be eligible for the award. In addition, a number of plaques will be granted to others who have done important work in this field, to signalize their achievements. Judging the merits of each submitted work will be members of the medical committee of the federation, including Drs. Richard N. Pierson, New York, Robert L. Dickinson, New York, Nicholson J. Eastman, Baltimore, Abraham Stone, New York, S. Bernard Wortis, New York, George D. Cannon, New York, Sophia J. Kleegman, New York, Harvey B. Matthews, Brooklyn, and H. McLeod Riggins, New York. The first award, a gift of Mrs. Albert D. Lasker, will be known as the Mary Woodward Lasker Prize. The closing date for the submission of entries for the awards will be June 1, 1944. According to Dr. John H. J. Upham, Columbus, Ohio, president of the Planned Parenthood Federation of America, it is hoped that the competition for the prize will serve to stimulate increased research in medical aspects of human fertility.

Pediatric Board Approves Nine Month Graduate Training.—The American Board of Pediatrics has ruled that three nine month periods of graduate training shall constitute acceptable training instead of the previous requirement of three full years of training. Two of the nine month periods must be spent in a pediatric center or, for a part of the period not to exceed six months, in a recognized hospital for the care of contagious disease. This ruling may be applied only in those instances in which the shorter periods of training were the direct result of the present wartime hospital programs for interns and residents. In issuing the ruling the board is forced to point out that the pressure of emergency conditions can in no way be allowed to lower the standards of its examination. It is contemplated that many candidates will find it necessary to seek additional postgraduate training after the war in order to be prepared properly for the examination. Officers of the board, chosen at its annual meeting November 19, are Drs. Edward B. Shaw, San Francisco, president, Donovan J. McCune, New York, vice president and Charles A. Aldrich, Rochester, Minn., secretary-treasurer. Dr. Alexander A. Weech, Cincinnati, was appointed to fill the unexpired term as a member of the board of Dr. Charles F. McKhann, Detroit, who resigned.

Section Meetings on the Ear, Nose and Throat.—The middle section of the American Laryngological, Rhinological and Otological Society will be held at the Hotel Cleveland, Cleveland, January 12. Speakers will include:

- Dr. Robert E. Howard, Cincinnati, A Statistical Study of the Relationship Between Tonsillectomy and Poliomylitis.
- Dr. John R. Lindsay, Chicago, The Cricopharyngeus Muscle in the Production of the Esophageal Voice (Roentgenologic Demonstration).
- Drs. Norman L. Hoerr and Fred W. Dixon, Cleveland, The Lymphatic Drainage of the Nasal Accessory Sinuses.
- Dr. Albert C. Furstenburg, Ann Arbor, Mich., Restoration of the Facial Nerve.
- Dr. Theodore E. Walsh, St. Louis, The Treatment of Laryngotracheobronchitis (with movie).
- Dr. Hans Brunner, Chicago, The Present Status of Diagnosis and Management of Ménière's Disease.
- Dr. Samuel Iglauer, Cincinnati, Two Cases of Osteomyelitis Treated with Penicillin.
- Dr. Thomas E. Carmody, Denver, Facial Injuries Related to the Nasal Sinuses and Oral Cavity.

The eastern section meeting will be held at the Waldorf-Astoria, New York, January 14, at which the following program will be presented:

- Dr. Gabriel Tucker, Philadelphia, Laryngofissure for the Treatment of Intrinsic Cancer of the Larynx: Indications, Technique and End Results.
- Dr. Paul B. MacCreedy, New Haven, Conn., Our Changing Conception of Acute Laryngotracheobronchitis.
- Dr. Frederick T. Hill, Waterville, Maine, The Management of Atelectatic Lung.
- Dr. De Forest C. Jarvis, Barre, Vt., The Part Nutrition Plays in the Production of Clinical Conditions in Otolaryngology.
- Lieut. Comdr. Frank L. Horsfall Jr. (MC), U. S. Naval Reserve, Virus Infection of the Respiratory Tract.
- Dr. Leroy A. Schall, Boston, Laryngocoele Complicated by Cancer: Case Report.
- Dr. Edmund Prince Fowler, New York, Head Noises in Normal and Disordered Ears, Significance, Measurement, Differentiation and Treatment.

At the western section meeting in Elks Temple, Los Angeles, January 22-23, the speakers will include:

- Dr. Gordon B. New, Rochester, Minn., Advances in the Care of Harlequin and Cleft Palate Deformities (with movies).
- Dr. Lorenz W. Ruddy, Sacramento, Calif., An Operation for the Correction of Postnasal Colossal Nasal Atresia in Children.
- Dr. Walter F. Mosher, Ventura, Calif., Adamantinoma of the Maxillary Sinus.
- Dr. Henry J. Profant, Santa Barbara, Calif., Temporal Arteritis.
- Dr. Isidore Friesner, New York, Otolologic Problems.
- Dr. Russell M. Decker, Pasadena, Calif., Facial Nerve Paralysis Associated with Acute Otitis Media.
- r. Benton N. Colver, Los Angeles, Sphenoid Sinus Headaches.
- r. Ben R. Dysart, Pasadena, Modern Viewpoint on Meckel's Ganglion Neuralgia.

The southern section meeting convenes in Atlanta, Ga., January 8, to hear the following program:

- Dr. James W. Jervy Jr., Greenville, S. C., Interesting Case Reports.
- Dr. Watt W. Eagle, Durham, N. C., Otolaryngologic Aspects of Bromine and Acetanilid Therapy.
- Dr. Robin Harris, Jackson, Miss., The Evaluation of Coagulation Time.
- Dr. Gilbert E. Fisher, Birmingham, Ala., The Use of Radium in Conduction Deafness.
- Dr. James Calhoun McDougall, Atlanta, Use of Sulfathiazole Powder with Radical Mastoid Operations.
- Col. Robert M. Colbert, M. O. C., Some E N T Cases in the Service.
- Dr. Alton V. Hallum, Atlanta, Dacryocystorhinostomy, Dupuy-Dutemps Technique.
- Dr. William D. Stinson, Memphis, Tenn., Further Considerations on the Use of Thiamine Chloride for the Relief of Cardiospasm.

Dr. H. Marshall Taylor, Jacksonville, Fla., president of the national group, will attend all the sessions.

LATIN AMERICA

Health Activities in Latin America.—On November 18 the state department authorized the Institute of Inter-American Affairs to finance a project entitled "Biostatistical and Epidemiological Information in the Other American Republics," to be undertaken by the Pan American Sanitary Bureau. Representatives named from each of the twenty American republics will submit a monthly report to the Pan American Sanitary Bureau of new cases and deaths for infectious diseases, including cholera, yellow fever, bubonic plague, typhus, smallpox, poliomyelitis, malaria, cerebrospinal meningitis, tuberculosis (all forms), typhoid, syphilis, leprosy and yaws. Reports will also be made on other public health data such as hospital facilities and the number of physicians in specified localities. It is contemplated that the representatives will make telegraphic reports to the bureau of all epidemics, outbreaks of diseases and other matters demanding urgent attention. On the basis of the reports received by the bureau, a monthly statistical news sheet will be prepared in English and Spanish and distributed throughout the hemisphere to institutions, governmental agencies and individuals interested in biostatistical and epidemiologic information. In addition, it is expected that the information thus obtained will also be compiled, analyzed, published and distributed to interested parties. The joint pro-

ject also provides for the translation and publishing of a Spanish edition of the Manual for Coding Causes of Illness. It is planned that 1,000 copies of this manual will be translated and published in the United States and distributed to various persons engaged in public health activities in the American republics, including the twenty representatives appointed by the Pan American Sanitary Bureau in connection with this project. The entire project will be directed and carried out by the bureau with the assistance of the Pan American Committee on Vital Statistics and Epidemiological Information, which is composed of representatives of the Pan American Sanitary Bureau, the United States Public Health Service, the Institute of Inter-American Affairs and the United States Budget Bureau. The committee will act in an advisory and consultative capacity.

Typhus.—In Guatemala a rigid typhus control program has been inaugurated, a feature of which has been the distribution of morbidity cards to physicians and mayors of Guatemala. By means of the cards 126 cases of the disease were reported during August and 108 during September. Public isolation buildings for the care of patients with infectious or communicable disease were constructed in San Cristoban Verapaz and San Juan Chamelco because of outbreaks of typhus there. During July and August 40 deaths from typhus occurred among a group of 1,000 textile factory workers and their families totaling between 5,000 and 6,000 persons.

Personal.—Dr. John W. Seddon, formerly medical officer with the field party in Brazil, returned to the United States on November 14 for reassignment by the War Department. Dr. Eugene H. Payne was transferred from his position as medical officer with the field party in Brazil to the Mica Mines Medical Assistance Program in the Rio Doce Valley, with headquarters in Vitoria. Dr. Gumersindo Sayago recently resigned as head of the Instituto de Fisiologia de Cordoba and professor of physiology of the Faculty of Medicine of Cordoba.

New Construction.—A new 32 bed hospital has been erected in Pucallpa, terminus of a motor highway across the Andes Mountains into Peru's upper Amazon country. The new building serves employees who are engaged in the development of the area for production of rubber, quinine and other economic resources. The hospital is one of a number of hospitals, health centers and dispensaries being established in the territory with the aid of the United States. The cooperative program is providing modern health services in the region for the first time in connection with colonization and development plans. Present plans call for the erection of five hospitals and fifteen dispensaries at convenient localities. A hospital is nearing completion at Iquitos to accommodate 80 patients.

Course in Tuberculosis.—A postgraduate course on epidemiology of tuberculosis will be given March 13-25 in the Instituto de Tisiología of the Faculty of Medicine of Montevideo. Included among the topics will be tuberculous pleurisy, history and clinical forms of tuberculosis, tuberculosis in Uruguay, significance of tuberculosis in diseases without recognizable microscopic tuberculous lesions, epidemiologic significance of organized antituberculosis crusades, antepartum and postpartum antituberculosis care and BCG vaccination, technique and results of bronchography, modern conception of pulmonary isthmus and question of clinical significance of pretuberculosis. Speakers will include Drs. Alberto L. Matteo, Alfonso Crisci, Juan B. Morelli, Aristeo Piaggio, Pablo Purriel, Abelardo Sáenz, Julio C. García Otero, Fernando D. Gómez, Cleopatra Epifanio, Pedro A. Barcia, Alejandro Artagaveytia, Armando Sarno, Abelardo Rodríguez, Ramón E. Marín Pittaluga, Alfredo Nario, Elbio Nattino, Juan J. Crottogini and Gumersindo Sayago. Drs. Víctor Armand Ugón, Américo Fossati and Juan Soto Blanco will be in charge of the surgical sessions. The address of the headquarters for registration is Secretaría del Instituto de Tisiología, Avda. Larranaga 1380.

FOREIGN

Voluntary Mobilization Urged for Influenza Epidemic.—The Ministry of Health has called on all district councils throughout Britain for a total mobilization of health visitors, school nurses, first aid post and rest center staff members and other agencies to combat the epidemic of influenza.

Society News.—Dr. Andrew Fergus Hewat was elected president of the Royal College of Physicians of Edinburgh at the annual meeting Dec. 2, 1943, and Drs. Charles McNeil, Lewis H. F. Thatcher, Alexander Ninian Bruce, David M. Lyon, William A. Alexander and David K. Henderson were elected to form the council for the ensuing year; Dr. Lyon is vice president.

LONDON

(From Our Regular Correspondent)

Nov. 27, 1943.

Penicillin

Penicillin excites such interest that a recent discussion of it at the Royal Society of Medicine produced a crowded meeting. Prof. Alexander Fleming reported that penicillin was the name he gave fourteen years ago to a substance which he obtained from the mold *Penicillium notatum* and which had an inhibitory effect on a variety of organisms. But the early filtrates were weak, and concentration was not possible before the brilliant work of Professor Florey and his colleagues in 1940.

Prof. H. W. Florey told the society that pure penicillin inhibited sensitive organisms in dilutions of 1 in 50 to 100 million and produced morphologic effects on the streptococcus in dilutions of 1 in 250 million. The sensitive bacteria, he said, included *Streptococcus pyogenes*, *Staphylococcus aureus*, *Diplococcus pneumoniae*, *Streptococcus viridans*, *Bacillus anthracis* and others, but the tubercle bacillus, coliform bacillus, *Proteus* and *Pseudomonas aeruginosa* were insensitive. Penicillin is nontoxic and is not inhibited by pus tissue autolysates, blood or serum. It is destroyed by acids and alkalis and, because of the hydrochloric acid in the stomach, cannot be given by mouth. It is rapidly absorbed from muscle and subcutaneous tissue. Rectal administration is ineffective, Professor Florey reported, because penicillin is destroyed by coliform bacilli. The dosage Professor Florey and his associates had used was 15,000 units every three or four hours. It was the only drug he knew of, he said, that gave no need to worry about overdose. The dosage mentioned would cure coccic septicemia. In local administration there must be adequate access to the infected parts. Professor Florey recently went to North Africa, where he cooperated with ten surgeons in the treatment of war wounds. They sewed up infected wounds and fractures, using penicillin locally and parenterally to prevent sepsis. Under ordinary conditions infection made closure of wounds older than six hours impracticable. He showed a film demonstrating the entire operation—from cleaning the limb with soap and water, trimming the skin edges and muscle, inserting tubes and closing the wound to the instillation of penicillin, which in some cases was repeated twice daily for five days. After ten days the stitches were removed. Out of 171 cases, complete union was obtained in 104, subtotal union in 60 and failure in 7. In some cases penicillin with sulfanilamide was blown on the wound.

Other speakers reported good results in the treatment of localized streptococcal and staphylococcal infection by direct application of penicillin. Bone infections, chronic sinuses, abscesses, arthritis, skin infections, infections of the eyes and lips, empyema, acute mastitis and acute infections of the hands have also been treated successfully, it was reported.

Col. Elliott C. Cutler, M. C., A. U. S., described 4 cases of severe fracture, 3 of the femur and 1 of the tibia and fibula, in which initial instillations were given of 10,000 to 20,000 units of penicillin solution. But in spite of continuous intramuscular applications of penicillin, gas forming organisms were detected in the wounds after three or four days and amputation was necessary. In all cases the condition of the patients was then satisfactory. Colonel Cutler felt that penicillin played a major part in the survivals. Gas gangrene antitoxin was also given. Subsequent speakers stressed the need for this.

Major J. N. Robinson, M. C., A. U. S., described the treatment of sulfonamide resistant gonorrhea with penicillin; 93 out of 95 patients were cured by a course of 100,000 units given in 15,000 unit doses every three hours. One of the 2 men not cured responded satisfactorily to a second course. Three patients with gonorrheal arthritis were also treated. One was

cured after 200,000 units of penicillin was given intramuscularly in 15,000 unit doses every three hours, but the others, who received only 100,000 units, were not cured.

Ban on Opium

The British government has decided to prohibit opium smoking in British and British protected countries in the Far East which are now occupied by the Japanese occupation. The countries chiefly affected are British Malaya, the Malay States and Hongkong. This step is the climax of a movement begun at the Hague International Conference of 1912, which gave rise to heated controversy with the United States. Thus a cause of disagreement is removed and a contribution is made to Anglo-American cooperation, particularly in the Far East. The final step from restriction to complete prohibition has been rendered possible because in China, from which much opium was smuggled into the territories mentioned, a vigorous campaign has been conducted by the present Chinese government against the cultivation and use of opium. At the stormy opium conference held at Geneva in 1924 and 1925 the American delegation sought to put an end to opium smoking by restricting production of the drug to scientific and medical needs. But there were practical obstacles, political and financial; among these were the production of opium for export by Chinese war lords, opposition by the poppy growing Persians and the fact that the administrations of Malaya and Hongkong derived substantial revenues from the opium monopoly. These considerations led the British and other governments to reject the American proposal, and the United States and China withdrew from the conference. Having rejected a measure which seemed impracticable, the British concentrated on control, but this did not satisfy the public conscience in this country. Fortunately the Chinese government, which refused to send delegates to the Bangkok conference of 1931, at last took active steps against opium smoking and production, while the Japanese army protected and exploited the trade.

Disease Follows Famine in Bengal

The Bengal government, with the assistance of the army, is engaged in fighting epidemics which have broken out in the wake of the Indian famine. Cholera alone has caused about 60,000 deaths during the sixteen weeks beginning July 10, a mortality of 60 to 70 per cent of the persons attacked. Besides cholera and intestinal disease due to unaccustomed foods, smallpox has broken out, and an unprecedented epidemic of malaria, including malignant forms of the disease, has appeared. An advance guard of army doctors, British and Indian, has taken the field to assist local health authorities. The Bengal government has also sanctioned the appointment for three months of 500 medical licentiates and 500 health assistants. It has also provided 24,000 pounds of quinine at controlled prices and 23,000 pounds for free distribution to malaria patients.

The government has taken means to combat famine by the importation of rice. Sir J. P. Srivasta, food member of the viceroy's council, has announced that every one from the viceroy down will be rationed as soon as a plan can be prepared. The central government is undertaking direct relief of victims of the Bengal famine.

Destruction of a National Library

Acting under orders, 600 German soldiers entered the Italian Royal Society's Library at Naples, soaked the shelves and books with gasoline, flung in hand grenades, and, having shot two guards who attempted resistance, kept the fire department at a distance while the library burned. About 200,000 volumes, including a most valuable collection of scientific periodicals and publications of learned societies throughout the world, were destroyed. The Germans also burned the great National Library at Naples. This contained over 1,000,000 volumes and

250,000 listed pamphlets, a collection of more than 4,000 incubula, many of them beyond price, 10,000 manuscripts and 11,000 autographs and autographed letters of famous people. One of the treasures of the Naples library was the unique collection of Greek and Roman papyri from Herculaneum. The Germans carried off what appealed to them and burned the rest. Other famous libraries have also been pillaged.

BRAZIL

(From Our Regular Correspondent)

Fingerprint Alterations and Clinical Dactyloscopy

With the recent publication of two papers on the pathology of fingerprints and dactylography, Dr. Leonidio Ribeiro of Rio de Janeiro and Dr. J. Paulo Vieira of São Paulo have brought to a successful conclusion the scientific work initiated by Israel Castellanos of Cuba, which proved that the patterns of the finger tip skin ridges formed by the dermal papillae are not immutable. In 1907 Dastre of the Academy of Medicine of Paris, seeking to appraise the several systems of human identification, advanced the value of fingerprinting, because, he said, the skin patterns of the finger tips are invariable from intrauterine life until after death. Professor Vervaeck of Brussels declared in 1908 that skin diseases and lesions such as herpes, eczema, impetigo and burns are able to modify the papillary patterns but only temporarily, since they are reestablished with the cure of these lesions. In his widely known *Treatise on Criminology* in 1931 Edmond Locard affirmed the principle of the immutability of the fingerprints and insisted on the point that they are not modifiable either pathologically or by the will of the individual himself. The first physician to point out that the fingerprints are modified by leprosy was Israel Castellanos of Cuba, who in 1923 proposed the use of the expression "clinical dactyloscopy" to characterize that branch of the study of fingerprints related to alterations of individual dactylograms in different diseases. Dr. Leonidio Ribeiro, professor of forensic medicine and director of the Rio de Janeiro Institute of Civil Identification, began in 1933 a series of researches to demonstrate the frequent alterations of the finger skin patterns as a consequence of lesions of traumatic or pathologic nature. In the first place, Dr. Ribeiro's work confirmed the findings of Castellanos regarding the alterations caused by leprosy and ascertained that these were caused by an abundant cellular infiltration of the derma, which contributed to shortening the height of the papillae. Further investigations showed that certain skin and nervous diseases lessen and even extinguish the papillary ridges—so much so that it is impossible to classify the fingerprint and so identify the individual. The most important scientific consequence of Dr. Ribeiro's findings was the possible use of analysis of fingerprint alterations for the diagnosis of some diseases, a fact which he announced when he began to notice the frequent occurrence of these alterations.

His recent paper includes several interesting cases of diseases discovered through the use of what he calls "dactylography." One of them is a case of leprosy discovered through study of the fingerprints alone. An illiterate Negro woman had been fingerprinted when opening an account in a savings bank in 1919. Fifteen years later, when she wished to withdraw her money, she had to be fingerprinted again, but she could not be identified as the true depositor because she presented a total destruction of the characteristic pattern of the papillary ridges. Dr. Ribeiro's help was requested to solve the difficulty, and he was so well acquainted with the picture presented by the fingerprints of leprosy patients that he immediately declared the woman leprosy without ever having seen her. The diagnosis was later confirmed by a specialist who recognized the patient as affected with leprosy. In another instance fingerprints taken recently at the Institute of Identification showed

a partial extinction of the papillary ridges in comparison with a former fingerprint filed at the institute ten years before. Although the man considered himself in good health, an examination demonstrated that he had a severe syphilitic infection, with a positive result for several serologic reactions and a characteristic buccal leukoplakia. Several other cases are described in Dr. Ribeiro's paper, presented with many illustrative documents under the title "Dactylography." Although these facts prove that the dogma of the immutability of the papillary patterns must be discarded, which may bring some practical difficulties, Dr. Ribeiro believes that on the other hand they will open new fields of use for this procedure as a distinct help to clinical medicine.

Dr. J. Paulo Vieira's monograph "Pathology of Fingerprints" shows that different physical and chemical actions are capable of so changing or disfiguring the papillary patterns that it is possible in several particular cases to state the occupation of a person by the analysis of fingerprints. This is clearly demonstrated by many illustrations included in the paper.

Caseosis in Leprosy

Dr. Eurico Branco Ribeiro recently reported to the Sociedade Paulista de Lepra a surgical study of nervous caseation in leprosy. The most frequent feature in leprosy is the rosary-like enlargement of the peripheral nerves. Sometimes, however, probably owing to a higher defensive power of the organism, the destruction of bacilli and formation of toxic substances lead to caseous necrosis of the nerves surrounded by granulomatous tissue. The area of caseosis gradually increases and involves nerves, perinerves, subcutaneous tissues and skin. The caseosis of the peripheral nerves in leprosy may be classified in four types. The first type includes cases in which the necrosis involves the skin. The second type includes cases in which there are multiple tumoral formations. The treatment in both these types is surgical removal of the nerve and necrotic tissues. The third group includes cases in which there is invasive necrosis of cutaneous branches of the peripheral nerves. The removal of the entire area is then necessary. In the fourth group, cases of smooth enlargement of the nerve, surgical therapy is limited to removal of the caseous material through an incision of the nerve.

Marriages

ROBERT VIVIAN EDWARDS to Miss June Olivia Ledyard DeWees, both of Coral Gables, Fla., November 18.

ERNEST W. FISHER, Bryson City, N. C., to Miss Mary Howard Crutchfield of Woodsdale, November 12.

RALPH BRETNEY MILLER, Washington, D. C., to Miss Anne Hetherington Upton of Mathews, Va., recently.

PERRY A. MORGAN JR., Ensley, Ala., to Miss Barbara Ruth Callaway of Birmingham, November 5.

HOWARD S. HUSSEY JR., Tarboro, N. C.; to Miss Jean Marie Miller of Hazelton, Pa., November 6.

THOMAS S. HARBIN, Rome, Ga., to Miss Margaret Foote Troutman of Atlanta, November 12.

ROBERT R. CROSS to Dr. Margaret M. Conlin, both of Toledo, Ohio, in Salina, Kan., November 5.

THOMAS PATRICK ALMY to Dr. Katharine Whitin Swift, both of New York, November 12.

HENRY GOUGH MONTGOMERY to Miss Martha Barlow, both of Dallas, Texas, November 5.

SAMUEL N. STONE JR., Ardmore, Okla., to Miss Love Porter of Oklahoma City recently.

EDWIN B. STROTHER to Mrs. Margaret Blackwell, both of Dallas, Texas, October 28.

PAUL D. OCHENRIDER, Wilkes-Barre, Pa., to Miss Ruth Ryce of Pittston, November 27.

LEONARD J. MCGEE to Miss Mabel Agnes Doyle, both of Philadelphia, recently.

Deaths

Armin Von St. George ☉ New York; Columbia University College of Physicians and Surgeons, New York, 1914; assistant professor of forensic medicine at the New York University College of Medicine; formerly instructor of pathology at his alma mater; specialist certified by the American Board of Pathology, Inc.; member of the American Association of Pathologists and Bacteriologists; member and past president of the American Society of Clinical Pathologists; a founder and vice president of the New York State Society of Pathologists; served in France during World War I and received two citations for distinguished service; served as assistant director of laboratories and pathologist, Bellevue Hospital; consulting pathologist, Medical Center of Jersey City, Jersey City, N. J.; on the staff of the Lenox Hill Hospital; in 1931 received from the Scientific Exhibit of the American Medical Association a silver medal for excellence of presentation of exhibit illustrating the effects of radium poisoning in the watch dial industry; author of "A Textbook of Pathology for Use in Schools of Nursing"; died November 20, aged 51, of cerebral thrombosis.

Frank A. Kelly ☉ Detroit; Detroit Homeopathic College, 1903; University of Michigan Homeopathic Medical School, Ann Arbor, 1919; president of the Wayne County Medical Society 1923-1924 and for many years treasurer of the society; formerly a member and president of the Michigan State Board of Registration in Medicine; fellow of the American College of Surgeons; a member of the founders group of the American Board of Surgery; veteran of the Spanish-American War; member, medical advisory board number 20, Selective Service; a member and past president of the city board of health; on the staffs of the Evangelical Deaconess Hospital, Receiving Hospital and the Highland Park (Mich.) Hospital; chief of staff, Grace Hospital; died December 10, aged 63, of left ventricular failure.

John Joseph Nutt ☉ New York; University of the City of New York Medical Department, 1897; Cornell University Medical College, New York, 1899; professor of orthopedic surgery at the New York Polyclinic Medical School and Hospital; specialist certified by the American Board of Orthopaedic Surgery, Inc.; member of the American Orthopaedic Association and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; at one time superintendent of the New York State Reconstruction Home, West Haverstraw, N. Y.; served on the staffs of the Willard Parker Hospital, New York, Nyack Hospital, Nyack, Long Beach Hospital, Long Beach, the Summit Park Sanatorium, Pomona and the New York Polyclinic Medical School and Hospital, where he died November 16, aged 73, of cerebral hemorrhage and arteriosclerotic hypertensive heart disease.

Charles Wesley Martin ☉ Woodmere, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1921; specialist certified by the American Board of Pediatrics, Inc.; past president of the Nassau County Medical Society; member and past president of the American Academy of Pediatrics; fellow of the American College of Physicians; consultant pediatrician, Long Beach Hospital, Long Beach, Meadowbrook Hospital, Hempstead and South Nassau Communities Hospital, Rockville Centre; attending pediatrician to St. Joseph Hospital, Far Rockaway, and the Nassau Hospital, Mineola, where he died November 16, aged 48, of bronchopneumonia.

John C. King ☉ Pasadena, Calif.; University of Nashville (Tenn.) Medical Department, 1874; fellow of the American College of Surgeons; one of the founders and past president of the San Bernardino County Medical Society; past president of the Riverside County Medical Society and the Southern California Medical Society; president of the California Medical Association in 1910; president of the high school board in Banning for twenty years; past president of the state board of medical examiners; at one time associated with the Indian Service; for many years surgeon for the Southern Pacific Railroad; died October 21, aged 90, of pneumonia.

De Witt Talmage Hunter ☉ Surgeon, Lieutenant Commander, U. S. Navy, retired, Washington, D. C.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1918; U. S. Naval Medical School, 1931; commissioned a lieutenant (jg) in the medical corps, Naval Reserve Force, on May 3, 1918; became a lieutenant in the medical corps of the U. S. Navy on Aug. 3, 1920 and

a lieutenant commander on June 30, 1931; died in the Union Memorial Hospital, Baltimore, October 28, aged 54, of coronary thrombosis.

Orville Reid Allen ☉ Lake Stevens, Wash.; Rush Medical College, Chicago, 1887; past president of the Snohomish County Medical Society; died October 23, aged 78, of angina pectoris.

John Herbert Allin, Fishers, Ind.; Trinity Medical College, Toronto, Ont., 1896; died in Indianapolis November 22, aged 81, of bronchopneumonia and fractured right hip due to a fall.

William S. Bickham, San Saba, Texas; University of Texas School of Medicine, Galveston, 1903; died at Paint Rock in November, aged 67, of myocarditis.

Edward Arnold Burkhardt Sr. ☉ Kansas City, Mo.; University Medical College of Kansas City, 1900; an Affiliate Fellow of the American Medical Association; at one time adjunct professor of obstetrics at his alma mater; on the staffs of the Menorah and St. Luke's hospitals; formerly on the staff of the Kansas City General Hospital; died October 11, aged 66, of hepatic cirrhosis and carcinoma.

Eben Proctor Clapper, Waynoka, Okla.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1901; member of the Oklahoma State Medical Association; died November 28, aged 74, of cerebral hemorrhage and pneumonia.

Paul Baker Clayton, Kansas City, Mo.; University Medical College of Kansas City, 1907; served during World War I; died October 9, aged 67, of arteriosclerosis.

William F. Clevenger ☉ Indianapolis; Medical College of Indiana, Indianapolis, 1894; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served during World War I; lieutenant colonel in the medical reserve corps, U. S. Army, not on active duty; on the staffs of St. Vincent's, Methodist and City hospitals; died November 20, aged 69, of coronary thrombosis.

La Rue Colegrove, Elmira, N. Y.; University of Buffalo School of Medicine, 1887; also a pharmacist; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; past president of the Chemung County Medical Society; for many years served on the city board of health; member of the board of managers of the Chemung County Sanatorium; consulting surgeon on the staff of the Arnot-Ogden Hospital, where he died November 11, aged 79, of virus pneumonia.

Lisle Leaholme Collins, Webster Groves, Mo.; St. Louis University School of Medicine, 1919; member of the Missouri State Medical Association; on the staffs of the Bethesda General Hospital, De Paul Hospital, Missouri Baptist Hospital and the Evangelical Deaconess Hospital, St. Louis, where he died October 14, aged 50, of embolism.

Annie G. Copeland, Wellesley, Mass.; College of Physicians and Surgeons, Boston, 1887; died September 6, aged 81, of hypertensive heart disease.

John S. Coughlan, Berkeley Springs, W. Va.; College of Physicians and Surgeons, Baltimore, 1908; also a druggist; died in the Washington County Hospital, Hagerstown, Md., November 17, aged 63, of injuries received in an automobile accident.

John H. Craven, Carl Junction, Mo.; Northwestern Medical College, St. Joseph, 1892; died October 27, aged 84, of chronic myocarditis.

Philip Henry Cronin, Houston, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1894; member of the State Medical Association of Texas; on the staff of St. Joseph's Infirmary, where he died November 10, aged 77, of coronary occlusion.

Howard Lewis Cushman ☉ Methuen, Mass.; Boston University School of Medicine, 1908; school physician; formerly member of the school committee and the board of health; member of the Selective Service System; died November 3, aged 57, of acute myocarditis and chronic interstitial nephritis.

Charles Albert Cutting, Tulare, Calif.; College of Medical Evangelists, Loma Linda-Los Angeles, 1940; diplomate of the National Board of Medical Examiners; commissioned a first lieutenant in the medical reserve corps, U. S. Army, on June 11, 1939 and dishonorably discharged on Oct. 10, 1942; died November 8, aged 32, of virus pneumonia.

Harry Preston Findley, Pasadena, Calif.; Rush Medical College, Chicago, 1899; at one time assistant superintendent of

the Massillon (Ohio) State Hospital; died October 29, aged 69, of coronary thrombosis.

Luther Wendall Fowler, El Dorado, Kan.; American Medical College, St. Louis, 1899; member of the Kansas Medical Society; on the staff of the Susan B. Allen Memorial Hospital; died October 18, aged 67, of carcinoma of the right lung.

Archibald E. Freer, Chicago; Rush Medical College, Chicago, 1891; died in the Augustana Hospital November 29, aged 81, of hypostatic pneumonia and acute cardiac failure.

Nicholas Amon Funderburk Ⓢ Union City, Tenn.; Emory University School of Medicine, Atlanta, 1922; member of the Medical Association of Georgia; died October 30, aged 48, of coronary disease.

Erwin Lowe Gill Ⓢ Shreveport, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1926; fellow of the American College of Surgeons; member of the staffs of the Tri-State Hospital, T. E. Schumpert Memorial Sanitarium, Shreveport Charity Hospital and the North Louisiana Sanitarium; suffocated October 31, aged 41, when his home caught fire.

Andrew Roy Hackett, Detroit; Drake University College of Medicine, Des Moines, 1912; served on the staff of St. Mary's Hospital; died November 16, aged 65, of coronary occlusion and chronic myocarditis.

Luther Anderson Hedges, Watseka, Ill.; Chicago College of Medicine and Surgery, 1909; member of the Illinois State Medical Society; served on the staffs of the Kankakee State Hospital, Kankakee, and the Iroquois Hospital; died November 15, aged 68, of coronary occlusion.

Harry Graves Hinckley Ⓢ Merrill, Wis.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1898; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; served as a member of the local school board, Lincoln county physician and health officer for the city of Merrill; at one time chief of staff, Holy Cross Hospital; died November 11, aged 68, of cardiac deficiency, due to emboli in lung, following an automobile accident.

Vardry Amon Hutton, Florence, Colo.; Hering Medical College, Chicago, 1903; member of the Colorado State Medical Society; served as president of the Colorado Board of Medical Examiners; died October 15, aged 76, of coronary occlusion.

Leonidas B. W. Johnson, Ireland, Ind.; Hospital College of Medicine, Louisville, Ky., 1885; member of the Indiana State Medical Association; died in the Welborn-Walker Hospital, Evansville, November 15, aged 85, of pneumonia.

Frank Weaver Kern, Seymour, Ind.; Louisville (Ky.) and Hospital Medical College, 1908; served during World War I; formerly associated with the Veterans Administration in Cleveland and on the staff of the Veterans Administration Facility, Brecksville, Ohio; died October 29, aged 62, of aortic stenosis.

Fred Edward Koch, Burlington, Iowa; St. Louis College of Physicians and Surgeons, 1901; member of the Iowa State Medical Society; served as Des Moines county physician; died November 13, aged 65, of leukemia.

Otto Edward Kress Ⓢ Louisville, Ky.; University of Louisville Medical Department, 1921; died October 16, aged 52, of coronary occlusion.

Benjamin Harrison Lamb Ⓢ Cincinnati; University of Cincinnati College of Medicine, 1915; served during World War I; died November 16, aged 54, of cerebral hemorrhage.

Oscar O. Larsen Ⓢ Detroit Lakes, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1907; served as president and secretary of the Northern Minnesota Medical Association; physician for the county Selective Service Board and a member of the volunteer medical corps of the council of national defense during World War I; city health officer; on the staff of St. Mary's Hospital; died suddenly, November 7, aged 66, of coronary occlusion.

Murry Herman Levine, New York; Columbia University College of Physicians and Surgeons, New York, 1918; also a pharmacist; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; formerly associate professor of otology at the New York Post-Graduate Medical School, Columbia University; on the staffs of the Harlem, Beth David and Beth Israel hospitals; died in the Barnes Hospital, St. Louis, November 19, aged 48, of bronchogenic carcinoma.

James Mary Joseph Allen Levins, Houston, Texas; Licentiate of the Apothecaries' Hall, Dublin, Ireland, 1913; at one time a medical officer in the British navy; died in the Hermann Hospital, November 10, aged 57, of diabetes mellitus.

Harold Barker Loughery, Muskegon, Mich.; University of Illinois College of Medicine, Chicago, 1922; member of the Michigan State Medical Society; president of the Muskegon County Medical Society; fellow of the American College of Surgeons; fellow in surgery at the Mayo Foundation, Rochester, Minn., from October 1927 until October 1930; on the staffs of the Mercy Hospital and the Hackley Hospital, where he died November 22, aged 47, of cerebral hemorrhage.

Lorne Taylor MacDougall Ⓢ Tunkhannock, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1919; served as medical director of Wyoming County; died September 5, aged 49.

John Joseph Madden, Brooklyn; Harvard Medical School, Boston, 1909; member of the Medical Society of the State of New York; also a pharmacist; specialist certified by the American Board of Otolaryngology; on the staffs of the Brooklyn Eye and Ear and St. Mary's hospitals, Brooklyn, and St. Vincent's Hospital, New York, where he died November 23, aged 61, of chronic coronary thrombosis.

Edward W. Martin, Kansas City, Mo.; University Medical College of Kansas City, 1901; member of the Missouri State Medical Association; served as local surgeon for the Missouri Pacific Railroad Company and the Chicago, Milwaukee and St. Paul Railroad; died in the Research Hospital November 9, aged 67, of cardiac failure and coronary occlusion.

Charles Ernest McNeil, Pennington Gap, Va.; Kentucky School of Medicine, Louisville, 1904; member of the Medical Society of Virginia; surgeon for the Louisville and Nashville Railroad; died October 26, aged 71.

James Herschel McNeill Ⓢ New Castle, Ind.; University of Nashville (Tenn.) Medical Department, 1906; at one time coroner of Morgan County; on the staff of the Indiana Village for Epileptics; died November 14, aged 63, of coronary disease.

Albert Baptiste McQuillan Ⓢ East St. Louis, Ill.; Washington University School of Medicine, St. Louis, 1903; past president of St. Clair County Medical Society; fellow of the American College of Surgeons; served during World War I; on the staff of St. Mary's Hospital, where he died November 12, aged 63, of myocarditis.

Theodore M. Moll, Detroit; Pulte Medical College, Cincinnati, 1891; served on the staff of the Monroe Hospital, Monroe, Mich., from 1924 to 1940; died November 20, aged 74, of arteriosclerosis.

George Roger Myers, Hurluck, Md.; University of Maryland School of Medicine, Baltimore, 1902; member of the Medical and Chirurgical Faculty of Maryland; on the associate staff of the Cambridge-Maryland Hospital, Cambridge, where he died October 7, aged 69, of cerebral hemorrhage.

Walter S. Nash, Knoxville, Tenn.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1889; member of the Tennessee State Medical Association; veteran of the Spanish-American War; medical examiner for the draft board during World War I; at one time alderman and councilman; served as chief of staff, Knoxville General Hospital; surgeon for the Southern Railway and the Louisville and Nashville Railroad; died November 13, aged 77, of pneumonia.

Little Berry Neal Ⓢ Jackson, Miss.; Memphis (Tenn.) Hospital Medical College, 1900; member of the Radiological Society of North America, Inc.; served during World War I; on the staff of the Mississippi Baptist Hospital, where he died December 1, aged 66, of coronary thrombosis.

Homer Lee Nickell, Morehead, Ky.; University of Louisville School of Medicine, 1910; served during World War I; formerly a member of the state legislature; died November 9, aged 57, of coronary occlusion.

Paschal J. Park, Cabot, Ark.; American Medical College, St. Louis, 1897; veteran of the Spanish-American War; died in the Army and Navy General Hospital, Hot Springs National Park, September 18, aged 76, of heart disease and generalized arteriosclerosis.

Douglas Amos Payne, Chicago; College of Physicians and Surgeons, Baltimore, 1887; member of the Illinois State Medical Society; at one time instructor in ophthalmology at the Illinois Medical College; died November 24, aged 86, of acute cardiac failure due to decompensated arteriosclerotic myocarditis.

Ewing Dwight Piper, Shadyside, Ohio; Starling Medical College, Columbus, 1905; member of the school board; died in the Martins Ferry Hospital, Martins Ferry, November 10, aged 65, of decompensated arteriosclerotic heart disease and cirrhosis of the liver.

James Albin Potts ☉ Pittsburgh; Western Reserve University Medical Department, Cleveland, 1879; died in the Shady-side Hospital November 15, aged 91, of cerebral hemorrhage.

Charles W. Ritter, McLean, Ill.; St. Louis University School of Medicine, 1903; member of the Illinois State Medical Society; member of the staff of St. Joseph's Hospital, Bloomington, where he died December 4, aged 66, of cerebral hemorrhage, arteriosclerosis and diabetes mellitus.

Frank Shackelford, Hope Hull, Ala.; Medical College of Alabama, Mobile, 1898; member of the Medical Association of the State of Alabama; died in the Fitts Hill Hospital, Montgomery, November 7, aged 75, of nephritis.

Joseph Lawrence Smith, Brooklyn; New York Homeopathic Medical College and Flower Hospital, New York, 1930; member of the Medical Society of the State of New York; died in the Adelphi Hospital November 12, aged 37, of a cerebral embolus following an appendectomy.

Matthew Thomas Smith, Chicago; Loyola University School of Medicine, Chicago, 1924; member of the Illinois State Medical Society; assistant clinical professor in surgery at his alma mater; senior on the surgical staff of the Mercy Hospital, where he died November 9, aged 45, of organic and rheumatic heart disease.

Archibald Alfred Southwick, Kendallville, Ind.; University of Wooster Medical Department, Cleveland, 1912; member of the Indiana State Medical Association; served with the American Expeditionary Forces during World War I; died in the McCray Memorial Hospital November 4, aged 58, of pneumonia.

Florence I. Staunton ☉ Peekskill, N.Y.;

Woman's Medical College of Pennsylvania, Philadelphia, 1905; an Affiliate Fellow of the American Medical Association; formerly on the staff of the Faxton Hospital, Utica; physician for St. Peter's parochial school; died in a Bangor, Maine, hospital October 16, aged 74, of coronary thrombosis.

Josiah S. Steiner, Bluffton, Ohio; Cleveland Homeopathic Medical College, 1898; served in France during World War I; died November 21, aged 71, of coronary disease.

William E. Stiles, East Northport, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1888; also a dentist; died recently, aged 79, of bronchopneumonia.

Gerald Hayden Stoner, Valparaiso, Ind.; American College of Medicine and Surgery, Chicago, 1905; at one time assistant professor of minor surgery at his alma mater; formerly served as county coroner and as a member of the city council; member of the board of education; on the staff of the Porter Memorial Hospital; died November 2, aged 69, of nephritis.

Walter Storm, Hope, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; died October 29, aged 74, of chronic myocarditis, hypertension and gangrene of the right leg.

Lyman Beecher Swormstedt, Washington, D. C.; Hahnemann Medical College and Hospital of Philadelphia, 1877; one of the founders and for many years on the staff of the National Homeopathic Hospital; died November 11, aged 90, of carcinoma of the prostate and bladder.

George Gordon Taylor, Maywood, Ill.; Northwestern University Medical School, Chicago, 1902; died November 13, aged 73, of cerebral hemorrhage.

Wilbur Andrew Uehren ☉ Aurora, Ill.;

Rush Medical College, Chicago, 1901; at one time health commissioner of Aurora; on the staffs of the Copley Hospital, St. Charles

Hospital and St. Joseph's Hospital where he died November 20, aged 65, of myocardial infarction due to coronary occlusion.

Daniel Frederick Wallenfelsz, Pleasant City, Ohio; Starling Medical College, Columbus, 1902; member of the Ohio State Medical Association; a director of the Old Pleasant City Bank; died in St. Francis Hospital, Cambridge, November 23, aged 72, of uremia.

John Bunyan Walling, Binghamton, N. Y.; Long Island College Hospital, Brooklyn, 1892; on the staff of the Binghamton City Hospital; died November 18, aged 76, of cerebral hemorrhage.

William T. Whaley, Glenwood, Ark.; Memphis (Tenn.) Hospital Medical College, 1898; died in a Hot Springs National Park hospital November 26, aged 78.

William Norman Williams ☉ Tabor City, N. C.;

Medical College of Virginia, Richmond, 1924; owner of the Williams Clinic Hospital; died in the Columbus County Hospital, Whitesville, October 25, aged 46, of injuries received in an automobile accident.

Arthur L. Winston, Colorado Springs, Colo.; Memphis (Tenn.) Hospital Medical College, 1887; member of the Colorado State Medical Society; died October 31, aged 79, of senility.

Samuel Paul Wise ☉ Americus, Ga.;

Medical Department of Tulane University of Louisiana, New Orleans, 1911; member of the South-eastern Surgical Congress; fellow of the American College of Surgeons; served with the American Expeditionary Forces during World War I; at one time part owner of the Wise Sanitarium, Plains; visiting surgeon on the staff of the Americus City Hospital; died, November 3, aged 59, of cerebral hemorrhage.

George Lawrence Wolf ☉ San Francisco;

College of Physicians and Surgeons of San Francisco, 1917; on the staffs of St. Joseph's Hospital and the French Hospital, where he died recently, aged 61, of carcinoma of the pancreas with metastases.

George R. Wycoff, McKees Rocks, Pa.; Kentucky School of Medicine, Louisville, 1892; member of the Medical Society of the State of Pennsylvania; died in Pittsburgh November 4, aged 77, of acute heart disease.

KILLED IN ACTION

Robert Morton Fuller, New York; Emory University School of Medicine, Atlanta, 1939; began extended active duty as a first lieutenant in the medical reserve corps, U. S. Army, on July 16, 1941 and was assigned to the 51st Infantry, Fourth Armored Division at Pine Camp, N. Y.; promoted as a captain; reported missing in action Nov. 8, 1942; aged 28; officially declared dead by the War Department Nov. 8, 1943.

Aaron Sydney Michelson, Cincinnati; University of Cincinnati College of Medicine, 1941; served as chief resident of the Jewish Hospital and assistant clinician in general medicine at the Cincinnati General Hospital; lieutenant (jg), U. S. Naval Reserve; reported missing in action, Nov. 13, 1942, while a medical officer aboard the destroyer U. S. S. *Laffey* following the third battle of Savo Island; aged 28; officially declared dead by the Navy Department on Nov. 14, 1943.

CAPT. ROBERT M. FULLER
M. R. C., U. S. Army, 1915-1943

LIEUT. (jg) AARON S. MICHELSON
(N.C), U.S.N.R., 1915-1943

ORCHIECTOMY IN THE TREATMENT OF PROSTATIC CANCER

To the Editor:—Exception may be taken to two statements made by Dr. H. L. Kretschmer (THE JOURNAL, Nov. 20, 1943, p. 755) in the report of his interesting group of patients with cancer of the prostate treated by bilateral orchiectomy. Dr. Kretschmer states first, "There seems to be a prevailing notion that, once a diagnosis of cancer of the prostate has been made, all that is necessary to effect a cure is to perform an orchiectomy." All will admit that a notion is hardly a proper subject for scientific discussion. It is of interest to us that this notion is prevailing, but it is not clear among what group it is prevalent. Certainly not among those who have read and understood the literature, which is extensive, relating to castration for prostatic cancer. So far as I am aware, no one has made any claim that any patient has been cured of prostatic cancer by this operation in the reports from the many urologists who have used it. In all of the papers from this laboratory emphasis has been placed on the large number of "failure cases." Properly many years must elapse before a cure of cancer can be claimed, although several of our patients are free from clinical and chemical evidence of the disease more than four years after orchiectomy.

Dr. Kretschmer writes further "From a review of the table it is evident that the results are anything but desirable." This table summarizes the findings in 11 cases of prostatic cancer in which orchiectomy was performed; in 10 of them at some time, in addition, transurethral resection of the prostate was done, which in case 2 was omitted. It is true that the results obtained were not spectacularly good in this series; 3 of the patients died within eleven months after orchiectomy, and others obviously have an advancing carcinomatosis. No description is given of the weight or microscopic appearance of the testes or of titers of sex hormones excreted in the urine, so that it is impossible to say whether the excised glands were producing effective amounts of androgen in these cases; when the testes are physiologically atrophic, no benefit can be expected from orchiectomy. However, in the "report of cases" it may be gleaned that there was temporary bettering in 8 cases following orchiectomy, such as improvement in appetite, in gain of weight, in decreased pain or in sense of well being; only in cases 3, 5 and 8 apparently was there no improvement. Obviously prostatic resection contributed to some of the improvement, but in 1 of the cases in which temporary benefit was obtained, this was omitted. I agree that the results in this small series were not optimal but believe that it is unjustifiable to say that the effects are undesirable when improvement, even temporary, occurs from any treatment in advanced cancer.

Since the endocrine treatment of prostatic cancer by both orchiectomy and estrogen administration was introduced by C. V. Hodges and me (*Cancer Research* 1:293 [April] 1941) and since there seem to be misconceptions concerning its efficacy, it may be clarifying to state our present position (*Science* 97:541 [June 18] 1943): "It must be emphasized that the results are not uniformly successful and that they fall into three groups; one group, less than 5 per cent of patients received no or slight benefit from endocrine treatment; the other groups, larger and nearly equal in number, obtained respectively an improvement pronounced but unsustained (less than eighteen months) or a pronounced and more prolonged regression of the disease. The improvement is greater than palliation, when technically the patient is merely made more comfortable in the face of advancing disease. The benefit in prostatic cancer often includes disappearance of the tumor, at least in the gross, and is considered as neoplastic inhibition. In clinical patients, castration seems to give somewhat better results than occur from

estrogenic therapy." Dr. Richard Chute has ably presented a useful concept in stating that if nothing more was accomplished from the endocrine treatment of advanced prostatic cancer than a decrease of man-pain hours, which often occurs, the results would be clinically desirable at the present. Often greater benefits occur.

CHARLES HUGGINS, M.D., Chicago.

[NOTE.—The letter of Dr. Huggins was submitted to Dr. Kretschmer, who replies:]

To the Editor:—Dr. Huggins takes exception to my statement that there seems to be a prevailing notion that, once a diagnosis of cancer of the prostate has been made, all that is necessary to effect a cure is to perform an orchiectomy. I made this statement based on my personal experience with internists, surgeons, urologists and general practitioners who consulted me because of the failure of castration in their patients to effect a cure of cancer of the prostate. Several patients have consulted me for the specific purpose of having an orchiectomy, having been told by their physicians that such an operation would cure their cancer. Again, I wish to state that this is my personal experience.

As I stated in my paper, it is not my intention to belittle the extensive studies that have been done on this subject by the Gutmans, Huggins and others but simply to report my experience with this treatment for cancer of the prostate.

I agree with the statement of Dr. Huggins that the results obtained were not spectacularly good. As Dr. Huggins quite correctly stated, 3 of the 11 patients are dead. A review of the chart discloses that in 5 patients there is anything but betterment; 1 patient complains of pain in the hips and legs with swelling of the legs and loss of weight; 1 patient complains of moderate pain in the sacral region extending down the leg; in 1 patient there is no change in the leg pains; 1 patient is bedridden with a loss of weight and increase in the bone metastases and now requires frequent doses of morphine, and the fifth patient has painful urination with gross bleeding; 2 of the remaining 3 patients show improvement, and the third patient states that he "feels well." The orchiectomies on the 3 patients who show some improvement and a state of well-being are of recent origin, having been performed four, seven and eleven months ago.

I have undertaken no scientific research on the question of how or why physicians, surgeons, urologists and the public acquire the impression that orchiectomy cures cancer. This I leave to others.

HERMAN L. KRETSCHEMER, M.D., Chicago.

ELECTROCARDIOGRAPHIC CHANGES IN ABDOMINAL DISEASE

To the Editor:—In their article entitled "Changes in the Electrocardiogram Induced by Acute Pancreatitis" (THE JOURNAL, Dec. 4, 1943, p. 892) Gottesman, Casten and Beller emphasize the diagnostic value of the electrocardiogram in this condition. They conclude that electrocardiographic changes are one of a triad which "should establish the clinical diagnosis of acute pancreatitis." This conclusion implies a specificity for such electrocardiographic abnormalities which is at variance with the experience of others and myself and which is contradicted by the authors' recognition that "changes in the electrocardiographic pattern have been observed in a variety of abdominal conditions particularly with those associated with disease of the biliary system."

Fitzhugh and Wolferth (*Ann. Surg.* 101:478 [Jan.] 1935) have presented several cases with gallbladder disease exhibiting striking electrocardiographic abnormalities similar to those encountered by Gottesman and his collaborators, which disappeared following cholecystectomy. In 1938 during the tenure

of a fellowship in the cardiographic laboratory at the Mount Sinai Hospital in New York, I carried out a study in collaboration with Dr. Arthur M. Master on electrocardiographic changes following major abdominal surgery. Electrocardiograms were taken in a series of 23 cases before and during the operation, and daily postoperatively. Following a variety of abdominal operations, electrocardiographic changes occurred in 18 of 23 middle aged and elderly men. The most frequent changes were depression of the ST segments and inversion of T waves in any or all leads, abnormalities identical with those described by Gottesman and his associates in their cases of pancreatitis. These changes usually appeared during the first two days postoperatively and persisted for a varying time. The electrocardiogram in most cases reverted to its control preoperative appearance by the time of discharge from the hospital. These abnormalities occurred in normal subjects as well as in those with clinical or electrocardiographic signs of heart disease and bore no relation to the type of operation, anesthesia or operative shock. Changes occurred in cases in which the postoperative course was normal but tended to be more noticeable in subjects with severe postoperative complications. These observations do not confirm the "control" studies of Gottesman, Casten and Beller, in which the electrocardiogram was not interpreted as abnormal in any patients after extensive surgical procedures on the gastrointestinal tract.

It is noteworthy that postoperative electrocardiographic changes, although frequently profound, are not usually associated with any clinical evidence of cardiac involvement. Post-mortem examination in 3 cases we studied showed no evidence of recent myocardial damage, although definite depression of the ST segment and T wave inversions were present in 2 of these cases. In 3 of the cases of pancreatitis cited by Gottesman, Casten and Beller an electrocardiographic diagnosis of acute myocardial infarction was made which was not substantiated by clinical findings or autopsy (case 2). It is important that electrocardiographic findings of the type described by the authors and observed by Fitzhugh and Wolferth and by myself should not be mistaken for coronary closure. Differentiation from coronary occlusion is usually possible by the absence of Q wave patterns and elevated ST segments which are typically observed in acute coronary occlusion (Master, A. M.; Gubner, R. S.; Dack, Simon and Jaffe, H. L.: *Arch. Int. Med.* 67:647 [March] 1941). The elevated ST segment cited in case 6 presented by Gottesman and his associates was probably different in origin from the changes noted in their other cases. Such elevation of the ST segment in all leads is typical of pericardial involvement, and it was remarked that "the pericardial cavity contained 50 cc. of brownish red fluid." Cardiac involvement in this case was further evidenced by the presence of gallop rhythm.

These criticisms do not detract from the interest of the findings described by Gottesman, Casten and Beller. They do, however, indicate that little or no specific significance is to be attached to such electrocardiographic abnormalities and that, accordingly, the value of the electrocardiogram in the differential diagnosis of pancreatitis may seriously be questioned. Depression of the ST segment and T wave changes have been observed in a great variety of conditions. It is probable that more than one factor plays a part in their genesis in acute abdominal disorders, e. g. shock with attendant reduced coronary flow, serum electrolyte changes and viscero-cardiac reflexes. Depression of the ST segments and T wave changes merely indicate a metabolic disturbance in the myocardium, not necessarily irreversible. Such changes relate particularly to the subendocardial region of the left ventricle, which is most vulnerable to metabolic disturbances, for reasons presented elsewhere (Gubner, R. S., and Ungerleider, H. E.: *Arch. Int. Med.* 72:196 [Aug.] 1943).

RICHARD S. GUBNER, M.D., Brooklyn.

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in *THE JOURNAL*, Jan. 1, page 57.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, Feb. 21-24. Sec., Dr. B. F. Austin, 519 Dexter Ave., Montgomery.

ARKANSAS: * March. Sec., Dr. D. L. Owens, Harrison.

CALIFORNIA: *Oral*. San Francisco, Jan. 20. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento.

CONNECTICUT: * *Medical, Written*. Hartford, March 14-15. *Endorsement*. New Haven, March 28. Sec. to the Board, Dr. Creighton Barker, 358 Church St., New Haven. *Homeopathic*. Derby, March 13-14. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

DELAWARE: *Written*. Dover, Jan. 11-13. *Endorsement*. Dover, Jan. 18. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

FLORIDA: * Jacksonville, June 26-27. Sec., Dr. W. M. Rowlett, Box 786, Tampa.

IDAHO: Boise, Jan. 10. Dir., Bureau of Occupational Licenses, Mrs. Lela D. Painter, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, Jan. 18-20. Supt. of Registration, Department of Registration and Education, Mr. Philip Harman, Springfield.

INDIANA: Indianapolis, May 2-4. Sec., Board of Medical Registration and Examination, Dr. W. C. Moore, 301 State House, Indianapolis.

KANSAS: Kansas City, Feb. 2-3. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.

MAINE: Portland, March 14-15. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

MASSACHUSETTS: Boston, March 14-17. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413-F State House, Boston.

MINNESOTA: * Minneapolis, Jan. 18-20. Sec., Dr. J. F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul.

MISSOURI: *Reciprocity*. Jefferson City, Jan. 24. Sec., State Board of Health, Dr. James Stewart, State Capitol Bldg., Jefferson City.

MONTANA: Helena, April 3-5. Sec., Dr. O. G. Klein, First National Bank Bldg., Helena.

NEVADA: *Endorsement*. Carson City, Feb. 7. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: Concord, March 9-10. Sec., Board of Registration in Medicine, Dr. D. G. Smith, State House, Concord.

NEW JERSEY: Feb. 15-16. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: * Santa Fe, April 10-11. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

NEW YORK: Albany, New York, Buffalo and Syracuse, Jan. 24-27. Sec., Dr. R. R. Hannon, Education Bldg., Albany.

OREGON: * Portland, Jan. 26-29. Exec. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland.

SOUTH DAKOTA: * Pierre, Jan. 18-19. Dir., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, Pierre.

WASHINGTON: * Seattle, Jan. 10-12. Dir., Department of Licenses, Mr. Thomas A. Swayze, Olympia.

WYOMING: Cheyenne, Feb. 7-8. Sec., Dr. M. C. Keith, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

CONNECTICUT: Feb. 12. Address State Board of Healing Arts, 250 Church St., New Haven.

DISTRICT OF COLUMBIA: Washington, April 17-18. Sec., Commission on Licensure, Dr. G. C. Ruhlman, 6150 E. Municipal Bldg., Washington.

FLORIDA: Gainesville, June 8. Sec., Dr. J. F. Conn, John B. Stinson University, DeLand.

IOWA: Des Moines, Jan. 11. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

MICHIGAN: Ann Arbor and Detroit, Jan. 14-15. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

NEBRASKA: Omaha, Jan. 11-12. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln.

NEW MEXICO: Feb. 7. Sec., Miss Pia Joerger, State Capitol, Santa Fe.

OREGON: Portland, March 4. * Sec., Board of Higher Education, Mr. C. D. Byrne, University of Oregon, Eugene.

RHODE ISLAND: Providence, Feb. 16. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Venereal Diseases: Quarantine of Infected Person "Confined or Imprisoned in Any Municipal Prison."

Under a Florida statute a person confined or imprisoned in any municipal prison is subject to being examined and treated for venereal diseases by the health authorities or their deputies. Such a person found infected with venereal disease may be compulsorily detained and treated to prevent the dissemination of the infection. The state board of health is vested with authority to make rules and regulations concerning the isolation and treatment of persons infected with venereal diseases. Acting by virtue of this statute the state board of health adopted regulations, one of which authorizes the health officer to quarantine infected persons either on the premises in which they live or in any other place, hospital or institution in the jurisdiction that may have been provided, and, if no such place has been provided, confinement in the county or city jail under quarantine may be resorted to.

The petitioner, a woman, was charged with being drunk and disorderly and was confined in the county jail awaiting her trial before a justice of the peace, who set her appearance bond at \$500. While so confined she voluntarily submitted to a physical examination which indicated that she was infected with gonorrhea. Thereon the state health officer ordered her quarantined in the county jail pending transfer to one of the quarantine hospitals operated by the state board of health for the isolation and treatment of persons infected with venereal diseases. The petitioner then brought habeas corpus to secure her release from detention under the quarantine. The trial court denied the petition for a writ of habeas corpus and ordered that she remain under quarantine under the supervision of the state board of health for treatment for said disease until she was cured and that on her cure the court would then consider an application to reduce the bond on the charges pending before the justice of the peace. The petitioner then appealed to the Supreme Court of Florida.

The sole question presented concerned the validity of the state statute and the rules and regulations of the state board of health under which the petitioner was quarantined. Generally speaking, said the Supreme Court, rules and regulations necessary to protect the public health are legislative questions, and appropriate methods intended and calculated to accomplish these ends will not be disturbed by the courts. All reasonable presumptions should be indulged in favor of the validity of the action of the legislature and the duly constituted health authorities. But the constitutional guaranties of personal liberty and private property cannot be unreasonably and arbitrarily invaded. The courts have the right to inquire into any alleged unconstitutional exercise or abuse of the police powers of the legislature, or of the health authorities in the enactment of statutes or regulations, or the abuse or misuse by the boards of health or their officers and agents of such authority as may be lawfully vested in them by such statutes or regulations. However, the preservation of the public health is one of the prime duties resting on the sovereign power of the state. The health of the people has long been recognized as one of the greatest social and economic blessings. The enactment and enforcement of necessary and appropriate health laws and regulations is a legitimate exercise of the police power which is inherent in the state and which it cannot surrender. The constitutional guaranties of life, liberty and property, of which a person cannot be deprived without due process of law, do not limit the exercise of the police power of the state to preserve the public health so long

as that power is reasonably and fairly exercised and not abused. The legislative authority in this legitimate field of the police power, like as in other fields, is fenced about by constitutional limitations, and it cannot properly be exercised beyond such reasonable interferences with the liberty of action of individuals as are really necessary to preserve and protect the public health. It has been said that the test, when such regulations are called in question, is whether they have some actual and reasonable relation to the maintenance and promotion of the public health and welfare, and whether such is in fact the end sought to be attained. Every reasonable presumption must be indulged not only in favor of the validity of legislative action in this important field but also in favor of the validity of the regulations and actions of the health authorities. As was said in 12 R. C. L. 1271:

Health regulations are of the utmost consequence to the general welfare, and, if they be reasonable, impartial and not against the general policy of the state, they must be submitted to by individuals for the good of the public.

It might be noted, continued the court, that after making its order the trial court announced that when the petitioner was cured he would reduce the bond set by the justice of the peace in the criminal proceeding probably to one hundred dollars or some other nominal sum.

Apparently, while awaiting the decision of the Supreme Court in the appeal from the decision of the circuit court, the petitioner applied for a release on an appearance bond pending the disposition of the appeal. The Supreme Court denied that application without an opinion. It now undertook to state its reasons for that denial. Our view, said the court, was that the petitioner was being held under a quarantine order, which is not a criminal proceeding and hence is not bailable. As soon as the petitioner is cured and released from quarantine, the court below has very properly announced that she will be promptly released from custody on a nominal bail bond to appear and answer the minor criminal charge for which she was arrested. The constitution of this state guarantees the right to bail in criminal causes, with one exception, namely, in capital offenses where the proof is evident or the presumption great. The court then adverted to the fact that the object of bail in civil cases is either directly or indirectly to secure the payment of a debt or other civil duty. But those reasons calling for bail in criminal and civil causes do not apply to an instance in which a person is detained on a quarantine order. To grant release on bail to persons isolated and detained on a quarantine order because they have a contagious disease which makes them dangerous to others, or to the public in general, would render quarantine laws and regulations nugatory and of no avail.

For the reasons stated, the order of the trial court dismissing the petition for a writ of habeas corpus was affirmed.—*Varholj v. Swecat, Sheriff, 15 So. (2d) 267 (Fla., 1943).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Pelvicoscopic Method of Uterine Suspension.—Harrell describes a new instrument which will allow the surgeon a direct visualization of the pelvic viscera without performing a laparotomy. He also shows how the Gilliam type of uterine suspension may be performed without open abdominal incision, by use of the pelviscope and special round ligament hook instrument. By performing this operation without open abdominal incision the patient may become ambulatory the first post-operative day and the period of hospitalization is reduced to one or two days.

Orchiectomy and Diethylstilbestrol in Carcinoma of Prostate.—During the past twelve months Herger and Sauer have carried out castration or diethylstilbestrol treatment or both on 82 patients with carcinoma of the prostate who were studied for a period of from three to twelve months. Sixty of the 82 patients were given diethylstilbestrol medication alone. Orchiectomy alone was carried out on 3 patients, and castration either preceded or followed by diethylstilbestrol was performed on the remaining 19 patients. Since 50 per cent of the patients receiving diethylstilbestrol exclusively responded with regression or softening of the prostate, the authors believe that estrogen administration without castration should have its place in selected cases of prostatic cancer. An indication for such treatment is present in patients (1) with operable carcinoma of the prostate who refuse radical operation, (2) with moderately advanced lesions who have little or no symptoms, (3) with comparatively low grade, malignant, well differentiated adenocarcinoma in whom progression of the lesion is slow, or (4)

who refuse castration or for whom orchiectomy is contraindicated. It is necessary to carry out reexaminations at frequent intervals, and castration should be carried out as soon as there is increase in size of the prostate with progressive infiltration into the pelvis, development of obstructive symptoms, increase in the serum acid phosphatase activity and other symptoms which suggest metastatic spread of the disease. Castration should be recommended for all patients with prostatic cancer in whom metastases are demonstrable and for patients with a type of lesion which has a tendency to rapid progression. In addition, castration should be carried out on patients who do not respond favorably to diethylstilbestrol administration. The value of combined diethylstilbestrol medication and orchiectomy is undecided. Although favorable results have been accomplished in numerous cases, the authors do not believe that castration or diethylstilbestrol treatment will result in cures. However, this method yields far more favorable results than palliative irradiation. Neither castration nor diethylstilbestrol treatment can replace surgical removal of cancer of the prostate in patients in whom the prostate is still encapsulated.

Regional Enteritis.—Fallis says that among the 180,000 patients admitted to the Henry Ford Hospital during the period between 1933 and 1943 there have been 27 patients who had regional enteritis as proved by operation and an additional 5 diagnosed on the basis of history and x-ray examination but not yet operated on. The author reviews observations in these 32 cases. He gained the impression that regional enteritis is on the increase and that it is more frequent in male than in female subjects, the ratio being about 4:3. Eighty per cent of the patients were under 40 years of age. Thirteen (40.7 per cent) of the 32 patients had previous appendectomy. One patient presented a massive intestinal hemorrhage as the principal symptom. A correct preoperative diagnosis was made in only one third of the patients. Resection is the operation of choice. The surgical mortality was 6.7 per cent. The terminal ileum was involved in 90 per cent of the cases. Thirty per cent of the patients on whom resection was performed had a recurrence and required subsequent resection.

Traumatic Avulsion of Skin of Penis and Scrotum.—Judd and Havens show that traumatic avulsion of the skin of the penis and scrotum is often caused by farm machinery. The usual history is that the patient's overalls have become enmeshed in the gears of the combine thrasher, and before the machinery can be stopped the clothing has engaged the pubic hair and avulsion of the skin has occurred instantly. Surgical restoration in these cases is now readily accomplished with modern methods of skin grafting, especially since the advantages of the Padgett dermatome have been proved decisively. The element of pressure on the grafted zone cannot be overemphasized. This may be obtained satisfactorily by a "doughnut dressing" cut from sponge rubber blocks and bound snugly in place with a roll of gauze. The observation was made that the catheter may not be quite as essential as it formerly was supposed. Recently patients have been able to do without the catheter early, and the consensus is that in cases observed in the future the catheter can be removed early. The point has been made that the tube acts as an extension mechanism for the penile shaft, but the proper application of the graft and the dressings may make this element superfluous. Therapeutic doses of chemotherapeutic drugs have been instrumental in overcoming sepsis of the traumatized tissue. If the patient is not seen immediately, it is well to employ sulfonamides in the preparatory period. The authors review 9 cases observed at the Mayo Clinic.

Effect of Sulfonamide Compounds on Nerve Regeneration.—Hammond and his collaborators designed experiments to determine the local effects of the sulfonamide drugs following simple nerve section, primary suture and suture delayed five days after the injury. The 58 cats used were killed at intervals of two, five, ten, fifteen and thirty days after the operation. Alternate longitudinal sections and cross sections of the nerve were stained by a modification of the Bodian silver method for nerve fibers, the hematoxylin and eosin method, Masson's trichrome technic and a silver impregnation method for argyrophilic and collagenous connective tissue. The regeneration of nerve fibers did not vary from the usual pattern in the presence of the sulfonamide compounds. Sulfanilamide, sulfathiazole, sulfapyridine and sulfadiazine do not appear to exert any chemical influence on the nerve regeneration. If these drugs are not rapidly absorbed they may offer a mechanical hindrance to the passage of regenerating fibers. The microscopic appearance of the sectioned nerve is a typical acute inflammatory reaction followed by reparative fibrosis. A typical foreign body reaction follows introduction of a sulfonamide compound into the wound except in the case of sulfanilamide, which is rapidly absorbed. The new nerve fibers are of small and medium size. Thick axons do not regenerate as such but produce a variable number of small and medium size fibers. The new fibers do not penetrate the old myelin sheath pathways but pass down beside them, presumably in a schwannian syncytium or between the sheaths of the endoneurium. A definite schwannoma was not observed. Primary suture of a nerve offers the best prognosis.

Trauma of the Larynx.—The Jacksons present the results of clinical observations on industrial, criminal, accidental and suicidal trauma of the larynx. So important is trauma of the larynx in the treatment of injuries of the neck that such injuries might well be divided into two classes according to whether the larynx is involved or not. Tracheotomy may be necessary for emergency control of cervical hemorrhage even in the absence of dyspnea. By enabling cannular maintenance of airway it permits compression in the neck to serve in emergency control

of hemorrhage. Endolaryngeal hemorrhage can be controlled by tracheotomy followed by direct laryngoscopic packing of the larynx. Tracheotomy, done early and low, is indicated in almost all cases of endolaryngeal trauma. In lacerated wounds of the neck involving the larynx the following points are important: (a) A cannula should not be worn in the wound more than a few hours if at all. To avoid this, low tracheotomy should be done at the earliest possible moment. (b) Débridement within the larynx is contraindicated. (c) The cervical wound should not be completely closed; a large channel down to the larynx should be packed open until perichondritis and chondral necrosis are controlled. (d) The laryngeal cartilage should not be stitched. (e) When the food passages are opened, a feeding catheter should be worn through the nose until the food passages are repaired by plastic or other methods; prevention of dehydration is even more important than feeding in these cases. (f) If sulfonamide compounds are to be used locally in cervical wounds with openings into the air or food passages, such openings should be momentarily closed with a pad of gauze to prevent entrance of excessive amounts of the drugs. In laryngeal fractures and crushes a core mold should be inserted immediately or within a few days to serve as an internal splint to maintain a good lumen and restore form. Usually their use can be commenced within a week or two after the occurrence of trauma. Pneumonia and edema of the lungs are rare complications. The signs on which such diagnoses have been based disappeared in most cases after bronchoscopic aspiration of obstructive secretions. Psychic trauma with vocal manifestations is curable by psychic treatment.

Influenza Among Immunized and Unimmunized Populations.—Hare and his collaborators say that groups of persons had been immunized with concentrated influenza A vaccine in various centers across the dominion of Canada from November 1942 through January 1943. The vaccine consisted of a tenfold concentrate of influenza A virus which had been grown in the allantoic fluid of the developing egg. An equal number of volunteers were given two doses of 1 cc. of saline solution to which had been added sufficient solution of formaldehyde to make the injections about as painful as those in which vaccine was injected. The volunteers were under the impression that two varieties of vaccine were being compared. All those who received the injections were asked to report any form of upper respiratory tract infection during the subsequent three months, or until the end of March. The standards adopted in the various centers varied somewhat. In Toronto and Edmonton, every case of upper respiratory tract infection, no matter how trivial, was studied. In Winnipeg and Vancouver, however, only cases of an influenzal nature were studied, those who merely had what appeared to be common colds being neglected. The studies were originally started in the hope of determining whether human beings immunized against influenza A were protected against infection with that virus. In view of the almost complete absence of influenza A in any of the centers where such immunization had been carried out, this question must remain unanswered. An epidemic of rather a mild character and somewhat atypical in symptoms did make its appearance in which serologic evidence indicated that about 23 per cent of the cases were due to influenza B. The incidence of influenza B in both immunized and control groups was approximately equal. No clinical differences between the cases diagnosed as influenza B and the remainder could be detected.

Respiratory Infections in a Military Camp.—The outbreaks studied by Hare and his associates comprise a relatively severe epidemic of the winter of 1940-41, one mild epidemic in the autumn of 1941 and three separate epidemics during the

winter of 1942-43. All occurred in Camp Borden. For the isolation of virus, the patient either gargled about 10 cc. of saline solution or had a similar quantity instilled into the nose by means of a rubber tube. Blood was taken as soon as possible after admission and again during convalescence. The titer of the neutralizing antibody of these serums was determined for influenza A and B viruses either by neutralization tests in mice or by the inhibition of agglutination of red cells. The first epidemic, that of 1940-41, was part of the widespread epidemic in which some cases were due to influenza A but with no identifiable agent responsible for the remainder. The epidemics in the succeeding year were not studied as completely as was desirable, but the wave studied was not due to influenza A or B. During 1942-43 there were three separate waves, each apparently due to something different. The first was undoubtedly not due to influenza A or B and no etiologic agent has been identified. About one fourth of the cases showed signs of lung involvement. This complication did not differ from the disease which has been reported as virus pneumonia, pneumonitis or primary atypical pneumonia of unknown origin. The second wave, in February 1943, was part of a widespread epidemic which appeared at various centers across the dominion. About 23 per cent of the cases were probably due to influenza B virus as judged by serologic tests. Actual isolation of influenza B was not achieved. The third wave was evidently due to influenza A. The first epidemic coincided with the usual outbreak of autumn colds, and a high proportion of patients suffered from what appeared to be a common cold for a day or two until the more acute symptoms set in. The symptoms which justified admission to the hospital may not have been quite typical of influenza; but as there were backache, headache and a short, sharp febrile illness in about 76 per cent of the cases it would be quibbling to describe the disease as anything but influenza. The remaining 24 per cent had the same general signs and symptoms but in addition developed signs in the lungs sufficient to justify the diagnosis of primary atypical pneumonia. There was close relationship between the patients who developed pneumonia and those who did not. It seems reasonable that the same etiologic agent was responsible for the infection in the two groups. A similar syndrome was seen in the second wave with about the same proportion of patients developing signs of lung involvement. There is little doubt that the connection between the common colds, influenza, febrile catarrh and primary atypical pneumonia, which occurred in the two waves, was due to a common etiologic agent in the waves. In the case of the first, this must still remain conjectural. But in the second wave a proportion of the patients were presumably infected with influenza B, some with A and two with both A and B, the remainder being also of unknown causation. The question arises whether all the patients were infected with the unknown agent, but some had a complicating infection with A or B viruses, whether the three agents influenza A, influenza B and the unknown agent were at work at the same time, each causing its own proportion of infections, or whether all the cases were due to influenza B but some failed to respond serologically. With the available evidence it is not possible to answer these questions.

Prompt Feeding Program for Bleeding Ulcer.—Rasberry and Miller present an analysis of 2,111 cases of grossly bleeding gastric and duodenal ulcer, including 75 personally observed, all treated with the prompt and frequent feeding

program as popularized by Meulengracht. The fundamental element of this treatment is prompt and frequent feeding. The feedings usually consisted of milk products, eggs, gelatin preparations, cereals, puréed vegetables and cooked fruits administered at least six times a day. Ground meats were often added after a few days. It has been generally unnecessary to make use of alkaline medication, though it has been used in some instances. Opiates have been avoided. To overcome shock an adequate fluid intake was urged. Transfusions have been given without hesitation. There was a gross mortality of 4 per cent and a net or corrected mortality of 1.9 per cent. The authors think that, except when coincidental perforation has occurred, better results, both as to the survival of the patient and as to his comfort during the period of his illness, are obtained by this regimen than by any other form of conservative treatment or by surgical intervention.

Resection in Congenital Megacolon.—Whitehouse and his colleagues gathered 29 cases of congenital megacolon or Hirschsprung's disease from the records of the Mayo Clinic between the years 1909 and 1941. Twenty-four of the 29 patients were males; that is, the ratio of males to females was about 5:1. Twenty-seven of the 29 patients had had severe obstipation since birth or infancy. The remaining 2 patients had had intestinal symptoms for several years. Subtotal colectomy was performed in all of the 29 cases. Seven, or 24.1 per cent, of the patients died as a result of the operation. It has been stated repeatedly that patients who are less than 3 or 4 years of age withstand surgical treatment poorly. This holds true for sympathectomy as well as for subtotal colectomy. Three of the 7 patients who died were less than 3 years of age. Every effort should be made to avoid surgical treatment until these patients become older. A follow-up study on the patients who survived the operation disclosed that the results of subtotal colectomy are long lasting and that few complications occur. Subtotal colectomy is the treatment of choice in cases of segmental congenital, idiopathic megacolon, in cases in which megacolon does not respond to sympathectomy or to medical treatment, and in cases in which it is due to chronic mechanical obstruction. Subtotal colectomy also is the treatment of choice in severe megacolon when the patients are males. Unless indicated by an emergency condition, subtotal colectomy is contraindicated in megacolon when the patients are infants.

Obesity Treated with Amphetamine Sulfate.—Kalb reports that 1,200 patients ranging in age from 12 to 63 years who were 10 to 124 per cent overweight were given amphetamine (benzedrine) sulfate. One hundred obese persons who did not receive medication served as a control group. Ten mg. of the drug was given daily; this was gradually increased to 20 or 30 mg. a day. In addition, a high protein diet ranging from 800 to 1,500 calories was prescribed. The average decrease in body weight was 26.4 pounds over a period of 11.2 weeks. The least amount of amphetamine sulfate used by any 1 patient was 70 mg. and the greatest quantity ingested was 5,030 mg. The average weekly loss in weight per patient was 2.4 pounds. In the control group the average period on the diet was 5.8 weeks, with an average weight loss of 22 pounds a week. Fifty patients who had been reduced to normal were placed on a maintenance diet ranging from 1,800 to 2,200 calories for a period of four weeks. Each patient received 20 mg. of amphetamine sulfate daily to determine if weight loss would result from the use of this drug alone. These patients failed to show any weight loss; in fact, each gained from 1 to 8 pounds (0.5 to 3.6 Kg.). Amphetamine sulfate has little or no effect on the blood pressure of obese patients with normal or elevated arterial tension. The pulse rate showed an increase in 26 per cent and a decrease in 8 per cent of the patients. The appetite was inhibited in approximately 40 per cent of the obese patients receiving amphetamine sulfate. The basal metabolic rate is not influenced by amphetamine sulfate in the doses given. The ingestion of amphetamine sulfate as such does not cause loss in body weight.

*An Outbreak of Dermatitis from Hair Lacquer. L. Schwartz—p. 1623.

Dermatitis from Hair Lacquer.—According to Schwartz, hair lacquers, which are used to keep stray locks in place, first were made of shellac either dissolved in alcohol or treated with borax or with triethanolamine. Dermatitis only rarely occurred

following the use of hair lacquer made from real shellac, but when the supply of shellac began to diminish on account of the war substitutes were used. Manila gum was the first substitute, but the supply of this also failed and cosmetic houses appealed to their shellac jobbers for a substitute. One jobber sold as a substitute for shellac a synthetic resin which had been used as a shellac substitute for wood varnish. The other chemical jobber when called on for a shellac substitute also furnished a synthetic resin. The composition of the resins was ascertained by questioning the two chemical concerns, each of which made one of them. This revealed that both resins, although obtained from widely different sources, were combinations of rosin and maleic anhydride. They differed only in that one manufacturer used in addition ethylene glycol, and that the other one, instead of actually using maleic anhydride to boil with the rosin, used fumaric acid, which is isomeric with maleic anhydride and changes rapidly to maleic anhydride on boiling. Undoubtedly the synthetic resins consisting of a combination of the maleic anhydride and rosin were the actual cause of the dermatitis, although the alkalinity of one of the products (pH 9) and the strong acidity of the other (pH 3) aided the penetration of the resin into the skin.

Anesthetic Infiltration of Sympathetic in Sequels of Traumas.—According to Bratek-Kozlowski, remarkable results have been obtained during this war in traumas of the extremities and nerves with anesthetic infiltrations of the sympathetic nerves. He reviews observations in 11 cases of injuries of the nerves and describes several interesting case histories. Explaining the technic of sympathetic infiltration, he first takes up that of the stellate ganglion, elucidating its anatomy on the basis of a diagram. He mentions numerous conditions for which infiltration of this ganglion has been employed and shows that nerve block by alcoholization is inadvisable. He uses from 10 to 15 cc. of a 1 per cent solution of procaine hydrochloride, as was recommended by Leriche and Fontaine. After evaluating the various approaches to the stellate ganglion he describes the lumbar sympathetic and the indications for and technic of the infiltration of this chain. He shows that infiltration of the sympathetic has a surprising effect in the sequels of injuries of

the extremities, particularly on the stiffness of the joints with edema, on the vasomotor or trophic disturbances and in certain painful sequels such as causalgia, cyanosis, sweating and the syndrome of Volkmann. It calms the pain instantaneously. Several minutes after the infiltration the voluntary mobility returns in the region of the paralyzed muscles; the arterial pressure increases and the oscillatory index increases. Sprain is in the majority of cases a vasomotor disorder of the nature of a reflex. From 10 to 15 per cent of cases are grave with important destruction. That is why the infiltration of the ligaments or of the lumbar sympathetic gives such excellent results.

Ossseous Metastases of Breast Cancer.—According to Bouchard, 180 cases of breast cancer have been treated at Royal Victoria Hospital since 1938. Of this number 37 showed roentgenologic signs of bone metastases, and death has occurred in 24 of these to date. These 24 cases are analyzed by the author. He found that 87.5 per cent of these metastases appeared in patients classed in groups 2 and 3 at the time the primary tumor was treated. The factor of age seemed to play no particular part either in the frequency or in the degree of the malignancy of these osseous metastases. The interval between the appearance of the primary tumor and the bony metastases was on the average three or four years, except in the patients between 20 and 30 years, in whom they seemed to appear in approximately half that time. The longer the interval, the longer is the survival. Osseous as well as pulmonary metastases must be systematically searched for, clinically as well as roentgenologically, before the patient is operated on. This search must be renewed in the course of the periodic examination, especially if the patient complains of so-called neuralgic or rheumatic pains. The search must be most thorough in the thorax, pelvis and lumbosacral part of the vertebral column. At least 75 per cent of the osseous lesions present an osteolytic aspect. An osteoblastic lesion indicates a slow growing metastasis. The prognosis must take into account other than skeletal metastases. Associated pleuropulmonary metastases make the prognosis much more unfavorable. Around 66 per cent of cases show subjective amelioration, while 26 per cent show objective improvement in response to palliative roentgen therapy. The patients with type 3 lesion should not be operated on; their primary and metastatic lesions should be irradiated. It is important to avoid forceful palpation of breast tumors and of their regional metastases, because such manipulations unfortunately are often the cause of dissemination of neoplastic cells.

Treatment of Bacillary Dysentery Carriers.—According to Hoagland and his collaborators the prevalence of the bacillary dysentery carrier state has been underestimated because the culture mediums formerly used were relatively inefficient and dysentery bacilli are often only intermittently demonstrable in feces specimens. This has resulted in the discharge of convalescent carriers from hospitals. An accurate evaluation of the efficacy of a drug in curing the bacillary dysentery carrier state can be established only if the newer, more efficient culture mediums are used and if many feces cultures are obtained over

as long a period as possible. In their own studies of patients who had had bacillary dysentery and of their contacts the authors found 45 carriers (12 convalescent and 32 chronic carriers) of *Shigella paradysenteriae*. A history of diarrhea was obtainable from 39 patients. None of the men had symptoms when admitted. Sulfaguanidine was given to 30 carriers and succinylsulfathiazole to 15. The daily dose of 20 Gm., divided into four doses given between 8 a. m. and 8 p. m., was given for six days. Routinely during treatment two leukocyte counts and hemoglobin determinations, two urinalyses and one determination of the sulfonamide compound in the blood were performed. The level in the blood was determined after three or four days of treatment. Bacteriologic examinations of feces were performed before treatment was begun and were resumed four days after cessation of treatment. Both "SS" agar and desoxycholate-citrate agar (including 5 mg. of paraaminobenzoic acid in each hundred cubic centimeters) were used for feces cultures. Material for culture was obtained from feces or from rectal swabs. Dysentery bacilli disappeared from the feces of every patient. A total of 503 feces cultures were examined. No significant toxic reactions attended the use of either drug, but the patient receiving succinylsulfathiazole experienced minor annoyances. The criterion of cure was a minimum of nine consecutive negative reports of feces cultures made after cessation of treatment.

Electroencephalography in the Navy.—According to Schwab, electroencephalography has three applications: The first is in the examination of applicants for naval service. Since electroencephalography takes forty-five minutes and requires special equipment, it cannot be done on all applicants. Only those who give a history of fainting or of recent head injury are referred for such examination. Candidates who have vague neurologic complaints, who sleep walk, and the like, may be referred. A normal record makes it possible to accept an applicant in spite of a history of an occasional syncope, whereas definitely abnormal waves suggest the advisability of rejection. The second application is in men actually in the naval service who have fainted or who have "spells." It aids in building up an accurate diagnosis of epilepsy. The third use is that of helping to fix the extent of intracranial damage to personnel who have suffered head injuries. The electroencephalogram is useful in helping the physician to determine when these men can be sent back to duty. Ninety per cent of the naval personnel with clinical epilepsy had abnormal electroencephalograms. Subjects with isolated syncopes who were clinically not epileptic usually showed normal records. In cases of mild head injury a normal record was the rule, and in cases of severe injury an abnormal record persisted long after the clinical signs had cleared up. The usefulness of electroencephalography in the diagnosis of, or in the elimination of a suspicion of, an epileptic tendency seems to have been thoroughly proved. Nineteen of 20 patients who had chronic seasickness showed normal electroencephalographic records. This method of examination is in no way a short cut and does not eliminate the necessity of a careful history and neurologic study.

Congenital Dilatation of Pulmonary Artery: Case. H. L. Heimann and M. M. Posel.—p. 512.

Local Chemotherapy in Rheumatism.—Scott thinks that previous workers have failed with local therapy for rheumatism because in fibrositis their dose was far too small but in the treatment of joints much too large. In the former 20 cc. rising to 50 or 60 cc. is usually well tolerated, whereas with joints 0.1 cc. to 0.2 cc. must not be exceeded. The author uses a 0 per cent solution of benzyl salicylate in oil. He observed at the rules of vaccine administration govern the weekly spacing, rising doses, negative phase and improving tolerance. The results obtained in a series of 96 consecutive and fully corroborated cases are assessed; 12 of these are briefly described. In 76 the results were good, in 14 fair and in 6 negative. The claim to innovation rests on matters of dosage and technic, the past neglect of which has obscured the value of local chemotherapy in chronic rheumatism.

War Wounds in Libyan Desert. J. Devine.—p. 187.
*Sulfaguanidine Treatment of Shiga Dysentery in New Guinea. J. J. Gard.—p. 188.

Sulfaguanidine in Shiga Dysentery.—Gard describes the results of treatment in 25 cases of bacillary dysentery due to *Bacterium shigae* in New Guinea. Although many patients with dysentery were admitted to the hospital during the campaign, Shiga infections were not observed until the closing stages. Since this type of dysentery is common in Japan, it is possible that the enemy was the source of infection. The Shiga dysentery encountered was on the average more severe than infections caused by *Bacterium flexneri* or the Boyd variety. It is not, however, safe to predict the type of infecting organism from the symptoms. In the treatment an initial dose of 2 or 4 drachms (7.5 or 15 cc.) of sodium sulfate solution was given. This was followed in two hours by 7 Gm. (14 tablets) of sulfaguanidine; then 3.5 Gm. (7 tablets) was given every four hours. Five doses were given each day until the number of stools in twenty-four hours was five or less, when the dose was reduced to 3.5 Gm. three times a day until the number of stools was normal for two or three days. In severe cases with much dehydration and exhaustion the initial dose of saline solution was dispensed with and 7 Gm. of sulfaguanidine was given immediately; this dose was followed by 3.5 Gm. given every four hours. One fourth of a grain (0.016 Gm.) of morphine and 1 one-hundredth of a grain (0.00065 Gm.) of atropine were given in all cases associated with abdominal pain. Fluids were given in the form of water, cordials, fruit drinks and barley water (from 4 to 6 pints [demiliters] a day). The patients were not starved. The average period during which

sulfaguanidine was administered was 13.5 days. Specific Shiga antitoxic serum was not used, nor was it required. No toxic effects were observed which could be attributed to sulfaguanidine, in spite of the large doses employed.

Ophthalmologia Ibero Americana, Buenos Aires

5:1-94 (No. 1) 1943. Partial Index

- *Therapy of Optic Neuritis with Nicotinic Acid. S. Barrenechea, R. Contardo, J. Arentsen and A. Jasmén.—p. 7.

Therapy of Optic Neuritis with Nicotinic Acid.—Barrenechea and his collaborators employed nicotinic acid in 5 cases of optic neuritis. The disease was retrobulbar in 4 cases. It was of alcoholic origin in 2 cases, due to focal infection in 2 cases and secondary to mumps in 1 case. The drug was administered by mouth in doses of 50 mg. each six times a day up to a daily total dose of 300 mg. for ten consecutive days. In the course of the first twenty-four or forty-eight hours central vision and visual field improved, the central scotomas disappeared and the subjective symptoms stopped. The author believes that optic neuritis whether retrobulbar or not is due to local avitaminosis which results from the increased use of the vitamins, especially nicotinic acid, by the body owing either to local or general infection or to increased destruction of vitamins by bacterial toxins. Because of the fact that the good results of nicotinic acid therapy are not permanent for as long as focal infection remains, it is advisable to carry on the proper examinations of the patient in the course of nicotinic acid therapy in order to control properly the infection after administration of nicotinic acid.

Mesenteric Cysts. P. L. Mirizzi, A. P. Cinelli and L. Ferraris.—p. 373.

Neurohepatic Degeneration.—Fracassi shows that, contrary to Wilson's and von Economo's belief, the degenerative process in hepatolenticular degeneration is not limited to the lenticular nuclei and the putamen but extends to the cerebral cortex, the white substance and the gray nuclei. He therefore thinks that neurohepatic degeneration would be a better term and includes under it not only Wilson's disease and the pseudosclerosis of Westphal and Strümpell but all cerebral degenerative nervous alterations caused by degenerative hepatic lesions. A case is described which could be considered Wilson's disease but which was really atrophic cirrhosis of Laënnec, probably due to a gastrointestinal disorder, since alcoholism or syphilis was absent. The patient showed neurologic manifestations ten years after the first symptoms of hepatic cirrhosis. The first neurologic manifestation was mild paralysis of the hands and legs. Later, speech became slow and hesitant and tremor of the hands developed. Clinical examination revealed an extrapyramidal syndrome with parkinsonian rigidity of the face and hand tremor, a moderate muscular rigidity, and dysarthria and tremor of the lips and tongue with difficulty in swallowing. There were also signs of a pyramidal syndrome: pronounced decrease in the strength of limbs, exaggerated tendinous reflexes, bilateral clonus of the foot and positive Babinski's sign in the left one. The patient also presented symptoms of cortical excitation in the form of epileptiform fits. He died of a pneumonia, and the necropsy showed atrophic cirrhosis of the liver with fibrous perihepatitis and interstitial splenitis as well as varices of the esophagus. There were atrophy of the cerebral cortex, laminar softening, atrophy of the striatum nuclei with softening and cystic dilatation of the perivascular spaces and areas of softening in the optic layer. Glial elements were abundant in the cortex and in the striatum nuclei. There were areas of circumscribed and diffuse denucleinization in the frontoparietal white substance.

Book Notices

The Principles and Practice of Industrial Medicine. Edited by Fred J. Wampler, M.D., Professor, Preventive and Industrial Medicine, Medical College of Virginia, Richmond. Cloth. Price, \$6. Pp. 579, with illustrations. Baltimore: William Wood & Company, 1943.

The impressive collection of thirty-three contributed chapters by authorities in the field of industrial health is in effect a genuine testimonial to the expanding scope and importance of the subject. Indeed, the statement is made that industrial medicine is as broad as medical practice and that no one individual can fully comprehend, let alone supply, the entire demands which industry as a whole places on medicine and hygiene. This book does supply the answers to many gaps in professional knowledge—gaps which the editor very pointedly attributes to failure of medical educators to recognize a most significant and valuable element in the distribution of highly necessary medical service. Excellent information is presented on these subjects, which all too often fall outside the customary range of medical interest and experience but about which physicians must be prepared to answer—accident occurrence and prevention, environmental medicine, illumination, fatigue, toxicology, workmen's compensation and rehabilitation. All of these important elements to a real understanding of industrial medicine are included, and the professional standing of the contributors is excellent evidence of dependable treatment. There are in addition chapters of major medical and surgical interest which will be equally revealing to nonprofessional readers.

A Study of Absenteeism Among Women. By S. Wyatt, R. Marriott and D. E. R. Hughes. Medical Research Council, Industrial Health Research Board. Emergency Report No. 4. Paper. Price, 2d. Pp. 12. London: His Majesty's Stationery Office, 1943.

This is a report of a limited study of absenteeism among women carried out on random samples of the personnel, over a six week period, at two royal ordnance factories. It was concerned with the amount and distribution of absenteeism rather than with its causes.

The following conclusions were reached:

1. Very few women were in the habit of losing one or two shifts a week.
2. Married women lost more time than single women.
3. The larger proportion of absences were from single shifts (68.3 per cent and 60.3 per cent in factory A and B respectively) but these accounted for only 34.9 per cent and 24.8 per cent of the total number of shifts lost.
4. Absenteeism was higher on the day shift than on the evening and night shifts.
5. Younger women (up to 25 years of age) lost more time than older women.

Principles of Behavior: An Introduction to Behavior Theory. By Clark L. Hull, Professor of Psychology, Institute of Human Relations, Yale University, New Haven. Cloth. Price, \$4. Pp. 422, with 84 illustrations. New York & London: D. Appleton-Century Company, Inc., 1943.

In this book the author attempts to integrate and systematize his previous work on the mathematical analysis of behavior. After an able introduction on the heuristic validity of "symbolic constructs" the author proceeds to assign specific symbols to various conative and integrative factors in behavior, such as (S) for "environmental energies," (s_U) for "unlearned receptor-effector-connections" and (s_H) for "habit." These and many other symbols are then combined into equations derived mainly from animal experimental data. In essence the formulas are designed to cover the consequences of the basic postulates that the behavior of an organism with a given neural organization depends "(1) upon the state of disequilibrium or need of the organism and (2) upon the characteristics of the environment, external and internal." Motivation is thus not neglected, but it is attributed to "hormone-like substances" and equated with various combinations of "potentiality of response evocation (s_{E_n})," "drive stimuli (S_n)" and other such constructs. As may be seen, the author's approach, thinking and style are uncompromisingly abstract and symbolic, so that the book makes most difficult reading, even with frequent cross references to

the glossary and index. However, Dr. Hull is to be commended for a courageous and searching attempt to express behavior in physiomathematical terms, and as such his work will be welcome to psychologists and biomathematicians with similar interests. Unfortunately, such pioneer work cannot yet be immediately useful to the clinician, who will probably have to wait many a generation for mathematical formulas significant for even the simplest impulses and idiosyncrasies of his friends or patients.

Health Instruction Yearbook 1943. Compiled by Oliver E. Byrd, Ed.D., Associate Professor of Hygiene and Director, Division of Health Education, School of Health, Stanford University. Foreword by Ray Lyman Wilbur, M.D., Chancellor, Stanford University. Cloth. Price, \$3. Pp. 308. Stanford University, Calif.: Stanford University Press; London: Oxford University Press, 1943.

The book has twenty chapters dealing with health as a social accomplishment, health as a social problem, nutrition and health, excretion and health, exercise and body mechanics, fatigue and rest, mental health and disease, heredity and eugenics, infection and immunity, chronic and degenerative disorders, habit forming substances, the care of special organs, safety, health and physical environment, health services and facilities, family health, school health, occupational health, community health services and trends and probabilities. There is a bibliography and an author index and a subject index.

In each chapter are varying numbers of excerpts of different length from publications of many agencies and by numerous authors. A typical section is that of chapter I, which deals with health as a social accomplishment. In this chapter are excerpts on improved health conditions in the decade 1930-1940, death records for 1942, health in 1942, health of the Navy, length of life, "We Outlive Our Expectation of Life," length of life almost doubled in six decades, infrequent deaths for some diseases in 1941, the American Army is healthy, medical progress in the American Army and "People Grow Taller in America."

One might find considerable cause for differing with the editor in his selection of material to publicize. In his chapter on health as a social problem, chapter II, he gives figures on Army rejections on physical and related grounds but does not choose to publicize related material, such as that published in the Statistical Bulletin of the Metropolitan Life Insurance Company, indicating that these rejections have little relationship to the health of the nation, being technical rather than clinical.

The items are numbered from the beginning of the book straight through in one sequence, so that the first item in chapter IV is number 49, and so on. In order to ascertain the full bibliographic information on each item it is necessary to turn to the bibliography. It might have been more convenient if the identification had been placed in direct relationship to the article. With both a subject and an author index this would have made for much easier reference.

This is an interesting beginning and can be a very useful venture. Yearbooks on public health have been tried before and have unfortunately found but a small sale, perhaps because most physicians are clinically minded. The recent upsurge of interest in public health and in health education may make this a more propitious time for a book of this kind. Naturally such a book represents the selections of one editor, possibly with advice from others. His selections also represent but a small fraction of the literature appearing each year. It should be a handy reminder and refresher volume, but it cannot be anything more. By itself it must necessarily give but a sketchy idea of what has happened during the year. A question arises as to the dating of this handbook. It is entitled "Health Instruction Handbook 1943." Obviously it cannot cover 1943, since it was received for review in October and therefore must have been compiled and prepared early in 1943. Most of the bibliographic dates are in 1942, and at least some of the material refers to editions in 1941. It would seem that this dating is at least somewhat misleading.

As an introductory volume this is interesting and useful. Undoubtedly experience and criticism will enable the editor to produce better material as the years go on.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

USE OF ERGONOVINE IN LABOR

To the Editor:—In a small hospital where expert consultation is not always close at hand is it safe to give ergonovine intravenously immediately after the delivery of the head? Also is it safe to give it either intravenously or intramuscularly at any time before the placenta is delivered?

Walter G. Bernard, M.D., Detroit.

ANSWER.—Ergonovine can be administered safely at the end of the second stage of labor if facilities for its use are available. The experience of the last three years in over ten thousand deliveries has indicated that the intravenous use of ergonovine to hasten the third stage of labor has reduced the incidence of complications in this period. The loss of blood has been greatly diminished, and the incidence of postpartum hemorrhage has decreased tremendously.

The hazard of using the drug at the end of the second stage of labor is the failure of expulsion of the separated placenta into the lower uterine segment and vagina and its possible incarceration in the lower contractile portion of the uterus, so that manual removal of the placenta becomes necessary. Proper timing in the intravenous use of ergonovine will reduce this hazard greatly. For its optimum effect the drug should be given as the anterior shoulder stems under the arch of the pubis, following which there should be a delay of about thirty seconds and the posterior shoulder delivered. The separation of the placenta occurs almost instantaneously as the uterus contracts down following the expulsion of the baby. The oxytocic effect produces a powerful uterine contraction, which results in the separation of the placenta and its extrusion into the lower uterine segment and vagina. It should be expressed from this locality promptly.

When ergonovine is given intramuscularly after delivery of the baby, about six or seven minutes is required for it to exhibit its action. By this time the placenta has separated spontaneously. The oxytocic effect is valuable in the expulsion of the separated placenta and in maintaining the uterus in good tone. There are no serious objections to the intramuscular administration of this drug after the delivery of the baby, although occasionally the incarceration of a placenta in the uterus does occur.

ONYCHOLYSIS

To the Editor:—A woman aged 42, who had always been in good health, about eighteen months ago began to have a looseness of the fingernails. There is no pain unless the loose ends are caught. The condition has been progressive, so that almost all the fingernails are loose with the exception of three. This does not affect her toenails. She has in the past been making soap and wonders if by any chance the lye could have been the cause of it. I have been unable to find anything in the textbooks or in the literature on this condition and wondered if you could give me the cause and suggest a treatment.

E. R. Sather, M.D., Alexandria, Minn.

ANSWER.—Since Oppenheim in 1909 (recounted by H. J. Templeton, Onycholysis, *THE JOURNAL*, Dec. 26, 1931, p. 1950) presented several cases of onycholysis in women doing laundry work, knowledge of the incidence of this nail dystrophy among industrial workers has grown. Schwartz and Tulipan (*Occupational Diseases of the Skin*, Philadelphia, Lea & Febiger, 1939, p. 541) list bartenders, bottle washers, cigar makers, confectioners, farm laborers, fruit workers, gardeners, milkers, vegetable cleaners and washerwomen as prone to this disorder. Soap makers are not listed; but the number of women who make their own soap is small and it seems possible that this job could precipitate an attack of onycholysis in a predisposed person. Templeton, in his report of a series of cases in bottle washers, shows that a definite predisposition exists, so that in two days of this employment the susceptible persons could be picked out. Others continued the work for long periods without such trouble.

In the case cited in the query, trauma of another kind or some constitutional factor must be suspected to have continued the trouble. Endocrine disturbances are the commonest predisposing factor, hypothyroidism and hyperthyroidism causing

many cases (Fox, E. C.: Diseases of the Nails, *Arch. Dermat. & Syph.* 41:98 [Jan.] 1940) with other endocrine disturbances seldom at fault. Fox calls attention to the intimate relation of vitamin deficiencies to endocrine disturbances, and in the discussion of this paper Becker emphasizes the effect of nervous disease, particularly neurodermatitis. Years ago Dubreuilh reported cases due to neurosis.

Even though the patient under discussion has no discernible sign of endocrine dysplasia, it may be justifiable to try a cautious course of thyroid extract. Heller (*Onycholysis*, *Handb. d. Haut- u. Geschlechtskr.* 13:113, 1927) suggests binding the loose nails with strong applications of tar, ichthammol or salicylic acid. Many patients with onycholysis have recovered after a course of roentgen treatments. If other means fail, this is justifiable. One may give weekly doses of 75 to 87 roentgens of unfiltered or lightly filtered rays, avoiding all irritating local applications during the period of treatment and for three weeks after the end of the course.

DURATION OF PROTECTION FROM ANTIRABIC VACCINATION

To the Editor:—If the information is available will you please tell me how long patients are protected who have been treated with antirabic vaccine? A number of patients here have been bitten by rabid dogs, have received Pasteur treatment and are wondering what protection they would have if bitten again in the near future. Carlyle Smail, M.D., Jerome, Idaho.

ANSWER.—How long antirabic vaccination protects against rabies is not known. There is lack of information on that point. From what is known about the specific protections produced by other forms of vaccination it lies near at hand to assume that the protection produced by antirabic vaccination may persist for months at least, but on account of the variability in the factors concerned there may be great variation in the effective persistence of protection. Accordingly it will be safest to advise revaccination if the patient is bitten again after even a short time. The second bite may be much more dangerous than the first.

EDEMA OF ANKLES ASSOCIATED WITH MENSTRUATION

To the Editor:—An unmarried woman with menstrual periods of three days occurring every twenty-eight days has been having considerable lower leg and ankle edema associated with her menstrual periods for the past sixteen months. There is no associated dysmenorrhea. Physical examination is essentially negative. There has been no response to eliminating the sodium radical from her diet the latter half of her menstrual cycle or from ammonium chloride or from either small doses of estrogenic substance or moderate doses of corpus luteum preceding her menstrual periods.

Robert S. Millen, M.D., New York.

ANSWER.—Salt and water retention may occur during the five days preceding menstruation, and with the onset of menstruation a diuresis may ensue. Such premenstrual edema usually responds well to a diet of low salt content and potassium citrate 10 cc. of a 20 per cent solution in fruit juice two or three times daily (total of 30 cc. daily) administered for five to six days prior to the onset of menstruation. Treatment with estrogenic substance or corpus luteum is of little value under such circumstances.

When edema is limited to the lower part of both legs as it is in the patient mentioned and when it has come on recently, one must also consider other causes which would aggravate the inherent tendency to retain salt and water at this time. The possibility of poor venous return, incompetent valves of the veins or venous obstruction deserves serious consideration, and appropriate tests for competent venous circulation should be made. It might also be helpful to measure the venous pressure in the lower extremities and compare this with the venous pressure in the arms. In most patients presenting the onset of swelling of both legs one ultimately finds either incompetent venous circulation, obstruction in the inferior vena cava or portal circulation, a mass in the pelvis, or local obstruction to circulation.

SNAKE VENOMS FOR RHEUMATISM

To the Editor:—What is your opinion of the use of moccasin venom for arthritis? Cyril E. Bousfield, M.D., Woolwich, Maine.

ANSWER.—Venom from several species of snakes, including the cobra, pit viper, water moccasin and copperhead, have been employed by various workers in the treatment of arthritis and other rheumatic disorders. Their virtues have not been impressive to physicians, although laymen have long favored ointments of snake oil and the stings of bees in the treatment of "rheumatism." The consensus among qualified workers today is that the scientific evidence for any of these venoms in the treatment of rheumatism is lacking. None of the snake venoms have any established place in the treatment of arthritis or rheumatism.

MANAGEMENT OF THE VENEREAL DISEASES IN THE ARMY

LIEUTENANT COLONEL THOMAS B. TURNER
AND
MAJOR THOMAS H. STERNBERG
MEDICAL CORPS, ARMY OF THE UNITED STATES

During recent months the rate of venereal infection in the Army has been below preceding peacetime levels and less than half that recorded during the first world war. Days lost per thousand men annually have dropped from 1,278 in 1940 to a level of approximately 400 at the present time. Nevertheless venereal disease patients accounted for approximately 2,824,000 hospital bed-days during the twenty month period from January 1942 to September 1943.

Determined efforts have therefore been made to reduce this manpower loss through measures aimed at the prevention of infection and through the more efficient treatment of the individual after infection. Since no sharp line can be drawn between prevention and treatment, responsibility for the formulation of policies and plans covering the entire venereal disease problem has been centralized in one branch of the Surgeon General's Office. The preventive program has been outlined elsewhere.¹ Briefly, reliance is placed on instruction of the individual soldier, on prophylaxis and, in cooperation with civilian agencies, on furthering those measures designed to reduce the potential sources of infection in the community. Gratifying results have been achieved in preventing venereal disease, as evidenced by the maintenance of a low infection rate, and new discoveries and changing administrative procedures have virtually revolutionized the treatment of these diseases.

In reviewing the treatment aspect of this program it should be pointed out that the Surgeon General's Office in initiating changes and promulgating new policies has had the benefit of the advice of the most eminent civilian specialists in the country, as well as those now in the armed services. Particular acknowledgment should be made of the valuable help received from members of the National Research Council.²

Read at the fifteenth annual scientific assembly of the Medical Society of the District of Columbia, Oct. 1, 1943.

From the Venereal Disease Control Branch, Preventive Medicine Division, Office of the Surgeon General, U. S. Army.

2. The Venereal Disease Subcommittee of the National Research Council comprises the following members: Drs. Joseph Earle Moore, chairman, John H. Stokes, Oscar F. Cox, Jr., Charles Walter Clarke, Neil Nelson, John F. Mahoney and Russell D. Herrold.

SYPHILIS

The treatment of syphilis presents a real problem to the modern army. Both the training program and actual campaigns are so arduous that soldiers who are physically under par fall short of requirements and serve as a drag on the group to which they are attached. Although symptoms caused by early syphilis can be quickly eliminated, treatment itself may result in morbidity, while continuation of treatment over long periods presents numerous administrative difficulties. Military requirements are best served by a system of treatment covering the shortest possible time consistent with safety to the patient and therapeutic efficiency.

Routine Treatment.—In July 1942, on recommendation of the venereal disease subcommittee of the National Research Council, the scheme of treatment of early and latent syphilis was substantially altered in two respects. First, arsenoxide (mapharsen) was recommended to the exclusion of the other arsenicals, and, second, the scheme of treatment was changed from alternating courses of an arsenical and a bismuth preparation given in weekly injections covering a period of one to two years to an intensified and shortened treatment scheme consisting of forty injections of arsenoxide administered twice weekly with additional injections of bismuth, covering a total of twenty-six weeks. The actual treatment scheme is given in the accompanying tabulation. The recommended individual dose of arsenoxide is 60 mg. and of bismuth subsalicylate 0.2 Gm. in oil.

This treatment scheme has been in effect only a little over a year, and no accurate data are available on the results in terms of the percentage of patients cured. Since this system is merely a modification of older ones and the total amount of arsenoxide administered (2,400 mg.) is about the same, it is assumed that the end results will not differ significantly, and that cures will be effected in not less than 85 per cent of cases of early syphilis.

The short term results have been excellent. From the standpoint of toxic reactions and practicability of administration, the newer scheme appears to be definitely superior to the older one. Persons with primary or secondary syphilis are hospitalized for a few days until open lesions have healed. Treatment is then carried on by unit medical officers.

Intensive Arsenotherapy.—Intensive methods of arsenotherapy, such as the five day intravenous drip proposed by Hyman, Chargin and Leifer,³ and the

3. Hyman, H. T.; Chargin, L., and Leifer, W.: Massive Dose Arsenotherapy of Syphilis by Intravenous Drip Method: Five Year Observations. Am. J. M. Sc. 197: 480 (April) 1939.

modifications employed by Schoch and Alexander⁴ and Thomas and Wexler⁵ would appear to offer many advantages to the armed services. The available evidence indicates that the results achieved by these methods in early syphilis are equal to those obtained by the routine treatment just described, but no intensive method has been adopted by the Army for routine use because of the enhanced risk of serious reaction and death that is inherent in these methods. In all the large series which have thus far been reported⁶ death has occurred in the proportion of 1 to approximately 250 patients treated, a mortality rate from treatment alone which must be compared with not more than 1 death in 5,000 when arsenoxide is given by routine methods.

The one day method of Simpson, Kendell and Rose,⁷ in which arsenoxide and fever therapy are combined, has the further disadvantage of being technically more difficult and no less risky than the five day intravenous

ment, and studies by numerous investigators both in the clinic and in the laboratory are rapidly determining those time-dose relationships which will yield a high proportion of cures in a short period of time with relative safety to the patient.

Mahoney and his co-workers⁹ have recently reported on the apparent effectiveness of penicillin in early syphilis. The import of this observation is stupendous and cannot be evaluated at this writing.

Biologic False Positive Serologic Tests.—Another point of importance which has been emphasized by Army experience concerns the frequency of biologic false positive serologic tests for syphilis. It has long been known that certain febrile diseases, such as malaria and respiratory infections, give rise to an increase in “syphilitic” reagin in the blood, sufficient in some instances to cause a frankly positive serologic test.

The Army is in a unique position to obtain further data on this perplexing problem. For the first time in history we now have a vast number of individuals under close observation, whose serologic status was determined prior to entering the Army, who since induction have been subjected to frequent inspections for the detection of venereal disease, and whose serologic status has been observed during the course of and subsequent to vaccination procedures and various acute illnesses.

The results of some of these observations have been presented by Arthur and Hale,¹⁰ Loveman¹¹ and Rosenberg.¹²

In brief, it is clear that the ordinary precipitation and complement fixation tests become positive in a high proportion—certainly not less than 15 per cent—of individuals following vaccination for smallpox with take and during the course of a great variety of acute febrile diseases. The “syphilitic” reagin commonly reaches its highest point within one to three weeks and then gradually declines, so that the serum will usually give a negative test within six weeks. Medical officers have therefore been cautioned that positive or doubtful serologic reactions occurring in individuals following vaccination procedures, or in those who have recently had acute infections, should not be considered indicative of syphilis. It is recommended that such individuals who have no conclusive history or clinical manifestations of syphilis be followed serologically and without treatment for a period of three months, serologic tests being performed each two to four weeks. At the end of this period those in whom the serologic reaction has reversed to negative are discharged from observation as nonsyphilitic; those showing a persistently positive test are regarded as syphilitic, and those still showing conflicting serologic reactions are subjected to further observation and study.

GONORRHEA

As a medical problem gonorrhea is totally different from that which it was five years ago. Approximately 70 per cent of persons with uncomplicated gonorrhea

drip. The system proposed by Eagle and Hogan,⁸ in which arsenoxide is given triweekly for a period of eight to twelve weeks, likewise appears to offer no advantages over more prolonged schemes; for while the mortality rate seems to be lower than with more intensive methods, milder reactions are sufficiently common to interfere seriously with the soldier's activities during the treatment period.

The importance of the contribution of Hyman and his co-workers in demonstrating the practicability of the five day treatment, if one is prepared to accept the risk, must not be minimized. This concept has already led to intensification of so-called routine treat-

respond within five to seven days to one course of sulfathiazole or sulfadiazine, another 10 to 15 per cent respond to a second course, and virtually all of the remainder can be cured within forty-eight hours with penicillin when that precious drug becomes more readily available.

The following data for the Army show the revolutionary changes that have taken place. During the years 1934 to 1937 inclusive persons with gonorrhea were hospitalized on an average of more than fifty days each. The average days of hospitalization declined to forty-five days in 1939, thirty-five in 1940 and twenty-two in 1941. Provisional data indicate that the average number of days lost per case is now under fifteen, and this figure can certainly be further reduced by the use of penicillin.

During the same period the frequency of complications has shown a striking decline. In 1937, 28 per cent of persons with gonorrhea developed some disabling complication. This proportion dropped to 12 per cent in 1939, 8 per cent in 1940 and 6.6 per cent in 1941. Current data indicate that less than 2 per cent of infected patients now develop complications. Facts of great significance are that with the increased use of sulfonamides in the treatment of gonorrhea the employment of local treatment for this condition has steadily decreased. The relationship of these changes in the management of gonorrhea to the duration of the disease and the development of complications is apparent.

Drugs Employed.—In the beginning of the sulfonamide era sulfanilamide was used in the treatment of gonorrhea. This was superseded by sulfapyridine and sulfathiazole. The latter drug, even in smaller doses than is now recommended, proved to be distinctly more effective and less toxic than sulfapyridine. Because of the factors of supply and cost, sulfathiazole is now employed routinely in the treatment of gonorrhea, although the use of sulfadiazine is also approved. There is no convincing evidence that for this purpose one is superior to the other.

Treatment is routinized as far as possible. For patients treated on a duty status and not hospitalized the recommended course of treatment is 4 Gm. of sulfathiazole a day for five days, given in doses of 1 Gm. four times daily. For hospitalized patients a higher dosage is recommended, as follows: 4 Gm. initially, followed by 1 Gm. every four hours day and night for five days, or a total of approximately 33 Gm.

Results of Treatment.—Data for the Army as a whole on the results of treatment of gonorrhea since the introduction of sulfathiazole are not yet available, but fragmentary reports from many stations and more complete data from a few of the larger stations permit certain generalizations. First, over three fourths of all patients with uncomplicated gonorrhea respond to one or two courses of a sulfonamide drug. Second, Negro patients respond more favorably than white. Third, the incidence of complications is exceedingly low. Fourth, toxic reactions from sulfathiazole present no serious problem, for even moderately severe reactions are uncommon and serious reactions are exceedingly rare. Fifth, when patients are treated on an ambulatory basis the end results in terms of propor-

tion cured, complications and drug reactions appear to be nearly as favorable as when treatment is given in a hospital.

The following data, accumulated over a period of months, give point to the foregoing statements: In a recent analysis of 2,100 cases of acute gonorrhea treated in one large station hospital¹³ of 804 white patients 81.5 per cent responded to two courses of sulfathiazole (20 Gm. each), while of 1,296 Negro patients 96.6 per cent recovered on the same treatment scheme. The proportion responding to the first course of sulfathiazole was white 65.2 per cent and Negro 91.8 per cent. A majority of the patients in this series were observed for three weeks or longer after the initiation of treatment. Epididymitis was observed in 1.1 per cent of cases and arthritis in 0.1 per cent. The incidence of each complication was slightly, though not statistically significant, higher in white than in Negro patients. Reactions from sulfathiazole, such as vomiting, elevated temperature, hematuria or dermatitis, were encountered in 1.1 per cent of this series.

From the same station¹³ an analysis of the results of treatment given on an ambulatory basis to 1,170 patients shows the following: Of 192 white patients 81.2 per cent were asymptomatic after two courses of sulfathiazole, and of 978 Negro patients 95.4 per cent were asymptomatic after the same treatment. Epididymitis was observed in 0.2 per cent. Drug reactions occurred in 0.4 per cent. These data are not strictly comparable to those cited for the hospitalized patients, since the patients treated on an ambulatory basis were largely drawn from the reception center where individuals are on temporary duty prior to proceeding to a permanent assignment, and follow-up observation was therefore not as complete.

In a series of 1,694 patients treated in another large station hospital¹⁴ by a dosage schedule approximating the larger (33 Gm.) of the two referred to, 82.4 per cent of the patients responded to the first course and another 10 per cent to a second course of sulfathiazole, giving a successful outcome in a total of 92.4 per cent with two courses. Epididymitis was observed in 0.5 per cent and arthritis in 0.3 per cent. Considerably more than half the patients in this series were Negroes.

In another large station hospital,¹⁵ of 770 patients with gonorrhea treated with the higher dosage schedule 85.4 per cent responded to the first course and 6.7 per cent to a second course, or a total of 92.1 per cent. Approximately 80 per cent of this series of patients were Negroes.

Of 1,117 patients treated for gonorrhea on a duty status at a number of stations of the Army Air Forces 75.7 per cent responded to two courses or less.¹⁶ Most of these patients were white.

It has been suggested by a number of observers that the proportion of sulfonamide failures is increasing, perhaps because of an increase in drug resistant strains of *Neisseria gonorrhoeae*. We have been unable to obtain evidence to support this suggestion.

Duty Status Treatment.—For many years soldiers with gonorrhea have been routinely hospitalized for treatment. Following a demonstration initiated and carried out under the supervision of Col. Sanford W. French, chief surgeon of the Fourth Service Command, the treatment of uncomplicated gonorrhea on a duty status was authorized for the Army as a whole in the early part of 1943. Present recommendations concerning duty status treatment call for one course of sulfathiazole to be given while the patient is carrying on his normal activities. If symptoms have not subsided within seven days after the beginning of treatment the patient is hospitalized and given a second course of sulfathiazole according to the higher dosage schedule mentioned.

While treatment of uncomplicated gonorrhea on a duty status is now widely practiced in the Army, there is still considerable discussion concerning whether in the long run hospital days are actually saved by this system. It is contended by some medical officers who have given thought to the problem that prompt hospitalization with the use of the higher dosage schedule will yield a lower proportion of sulfonamide failures. Data adequate to permit a conclusive answer on this point are not yet available. It is our opinion, however, that treatment of uncomplicated gonorrhea on an ambulatory basis is wholly practicable under most circumstances, and that the results are significantly inferior to those obtained by hospital treatment only when adequate care is not or cannot be taken to insure that the infected soldier receives his medicine at the proper time and in the proper dosage. There is no evidence indicating that ambulatory treatment is accompanied by an increase in the incidence of complications.

Despite theoretical arguments frequently advanced concerning the danger of patients with gonorrhea to their barrack mates, we have yet to learn of a case of gonorrhea acquired from toilet seats, towels or by means other than sexual contact. Gonococcic ophthalmia, even among persons with gonorrhea, has been encountered extremely rarely. In order to protect the civilian community, patients with gonorrhea are restricted to the organizational area for three weeks after the disappearance of urethral discharge.

Sulfonamide Failures.—It is estimated that fully 50 per cent of the total days lost from duty because of gonorrhea are accounted for by the 10 to 20 per cent of those patients who fail to respond to two courses of sulfathiazole or sulfadiazine and are classed as sulfonamide resistant. These patients were exceedingly difficult to cure by means formerly available. Some seem to respond to continuing doses of sulfonamides, others appear to be benefited by local instillations of a silver salt, while some become asymptomatic after many weeks with little or no treatment. Until the advent of penicillin, fever therapy—eight hours of continuous fever at a temperature of 106 F.—combined with sulfonamides by mouth was the only method by which resistant patients could be promptly cured.

In order to reduce the manpower loss occasioned by these resistant patients, facilities for fever therapy are provided in general hospitals. However, this method of treatment is expensive in terms of personnel and equipment; it is not without risk to the patient and

can be justified only on the basis of military necessity. It is hoped that enough penicillin will soon be available to treat all of these patients and render it unnecessary to use fever therapy.

Penicillin.—This remarkable drug bids fair to reduce gonorrhea to the status of an inconsequential infection. On receipt of reports from Mahoney prior to publication of the observations made by him and his co-workers¹⁷ the Army initiated in May 1943 clinical studies in a number of hospitals with a view to determining the smallest dose of penicillin which appears to yield a high proportion of cures.

Groups of patients proved to be refractory to at least two courses of sulfathiazole or sulfadiazine and in some cases to fever therapy were treated with a total dosage of 160,000, 120,000, 100,000, 80,000 and 40,000 Oxford units, respectively. Approximately half of each group was given 10,000 units every three hours, and the other half 20,000 units at the same interval. Most treatments were given intramuscularly, and this route was shown to be superior to intravenous administration.

The results of these clinical studies will be reported in detail elsewhere. To summarize them briefly, better than 95 per cent of each group receiving a total dosage of 80,000 units or above were cured as determined by culture of the prostatic secretion at the end of seven, fourteen and twenty-one days after the initiation of treatment. Even with 40,000 units there were less than 15 per cent failures.

In those patients who responded, cure was effected with extraordinary rapidity, subjective and objective improvement occurring in most cases within twenty-four hours after the beginning of treatment. Cultures were often negative in twenty-four hours and almost invariably so in forty-eight hours. In a fair proportion of treated patients a very slight mucoid discharge persisted for one or two weeks, but no organisms were demonstrable on smear or culture and the slight discharge is regarded as being of no significance. Failures on any of the dosage schedules employed were usually evident by the end of the first week. Some penicillin resistant patients simply failed to show any improvement, while others improved symptomatically and then relapsed. Relapses were rarely observed after ten days. Persistent infections in the absence of symptoms were only rarely observed, and these occurred principally with the lower doses. Nearly all of a number of patients who failed to respond to the first course of penicillin were cured by retreatment with 10,000 units of penicillin every hour for ten doses.

In view of the limited supply of penicillin, use of the drug is being largely restricted to theaters of operation where an effort must be made to keep every soldier on the job. While a total dosage of 80,000 to 100,000 units per case gives better results, a course of treatment consisting of 10,000 units intramuscularly every three hours for five doses, or a total of 50,000 units, is recommended, with recognition that 10 to 20 per cent failures may be expected at this dosage level. Failures with the first course are retreated with penicillin, a total dosage of 100,000 units per case being used.

17. Mahoney, J. F.; Ferguson, Charles; Buckholtz, M., and Van Slyke, C. J.: The Use of Penicillin Sodium in the Treatment of Sulfonamide Resistant Gonorrhea in Men, *Am. J. Syph., Gonorr. & Ven. Dis.* 27: 525 (Sept.) 1943.

Further studies are being carried out with a view to determining those factors that enhance the chance of cure.

Local Treatment.—For many years Pelouze¹⁸ has been pointing out that complications of gonorrhea often occur as a result of faulty treatment rather than as a natural consequence of the disease, and he has labored to impress on physicians the importance of avoiding manipulative procedures which might traumatize the urogenital tract. During the past year the Army has provided a convincing demonstration of the soundness of that point of view.

As might be expected in a field which is changing so rapidly, practice varies widely from one hospital to another. At one end of the scale are those hospitals in which gonorrhea is treated in the medical service and the patients receive no local treatment whatever. At the other end of the scale are those in which manipulative procedures, instillations and irrigations are utilized in addition to the sulfonamides by mouth. It can be said categorically, it is in those Army hospitals in which reliance is placed on internal medication and forced fluids to the exclusion of local treatment that the best results are being obtained. Nothing appears to be gained by urethral instillations, prostatic massage or the passing of sounds in the ordinary case of uncomplicated gonorrhea, and the proportion of complications appears to be significantly higher where these procedures are employed. Fortunately, practice in the Army is veering sharply away from these methods.

Cases occur, of course, in which some local treatment is indicated, but these are the exception rather than the rule. If a patient with gonorrhea has phimosis or urethral stricture, these anatomic defects must be corrected; but meddling manipulation serves no useful purpose.

Tests of Cure.—Formerly it was the practice in the Army to rely entirely on smears or cultures of the urogenital fluids in determining cure of gonorrhea in the male. These procedures are no longer required in cases which respond promptly to sulfathiazole. Reliance is now placed principally on clinical observation in these cases. The reasons for this change are twofold. First, experience over a period of many months revealed that among patients with uncomplicated gonorrhea who responded promptly to sulfathiazole and who continued to show no evidence of urethral discharge only a small percentage showed gonococci in the prostatic fluid by smear or culture at the end of the third week. Since a large amount of laboratory work was being done in order to detect a negligible number of latent infections, the results were believed not to be commensurate with the work involved. Secondly, for the reasons cited in the foregoing section it is highly desirable to avoid prostatic massage whenever possible.

Patients with acute gonorrhea who respond to sulfathiazole are observed clinically and with the aid of the two glass test of the urine for three weeks and are discharged from observation if asymptomatic at the end of that period. Smears and cultures of the prostatic fluid are still made as a test of cure in those patients who are sulfonamide resistant.

CHANCROID

Among troops stationed in this country chancroidal lesions comprise about 6 per cent of all cases of venereal disease. In certain theaters of operation these lesions present a greater problem. In somewhat over 50 per cent of patients with lesions clinically resembling chancroid there is a favorable response to sulfathiazole. In the remainder the lesions are often quite refractory to treatment. Since the diagnostic methods usually available are often none too reliable, it is possible that more than one etiologic entity is being encountered. Further clinical and bacteriologic studies on this problem are needed.

OTHER VENEREAL DISEASES

Lymphogranuloma venereum and granuloma inguinale are commonly considered as the other members of the group of venereal diseases. The incidence of these two diseases in the Army is relatively low and they have thus far presented no serious problem.

CONCLUSIONS

From recent Army experience in the management of venereal disease, several conclusions may be drawn. First, while the treatment of syphilis has been greatly improved, no method of therapy yet developed is entirely satisfactory. The problem is of sufficient importance to justify speedy exploration of all new leads.

Secondly, biologic false positive serologic tests occur often enough after vaccination procedures and following acute febrile illnesses to constitute a serious diagnostic problem. Under such circumstances follow-up observations are necessary in order to avoid treating individuals for syphilis in the absence of infection.

Thirdly, the treatment of gonorrhea has become largely one of internal medication. Urethral instillations, prostatic massage and the passage of sounds are contraindicated in the early phase of the disease for they frequently induce complications.

Fourthly, penicillin promises materially to change the management of gonorrhea. When supplies of this drug become readily available, sulfonamide resistant gonorrhea should no longer be a problem, and the necessity for long continued treatment or for the use of fever therapy in these cases will have been eliminated.

Finally, certain administrative practices and social attitudes, valid perhaps in an earlier day, are now hampering the full application of the remarkable scientific advances made in the treatment of these diseases. Medical treatment is now so effective that diseased persons can promptly be rendered noninfectious and returned to duty as functioning members of the group. Any measures, therefore, which tend to keep the infected person away from medical care are directly opposed to the best interests of the individual, the organization to which he belongs and the community. Stoppage of pay, prejudicial treatment from employers or superiors, restrictions on advancement, can only serve as powerful factors tempting the individual to conceal his infection and delay treatment until its effectiveness is reduced. The sooner discriminatory practices are abolished and syphilis and gonorrhea regarded as other infectious diseases, the sooner will it be possible to realize the full benefits of recent scientific progress.

SUBLINGUAL ADMINISTRATION OF DRUGS

ROBERT P. WALTON, M.D.
CHARLESTON, S. C.

In discussions of therapeutic technics there is frequently recurring opinion to the effect that any of the potent nonirritant drugs may be effectively administered by simple application to the oral mucosa.¹ Very few drugs, however, are routinely used in this way in regular practice. Recently there were recommendations, both in this country² and in England,³ that morphine be administered sublingually in those wartime emergencies in which hypodermic injections were not possible. The recommendation was challenged⁴ and, fortunately, has not been generally accepted. These contradictory opinions demonstrate that there does not exist any clear and general recognition of the scope and limitations of this particular therapeutic technic.

Penetrability of Drugs

Alkaloid	Fat Solu- bility, Mg./Cc.	Water Solu- bility, Mg./Cc.	Fat- Water Solu- bility (Dis- tribu- tion) Cocilli- taneous	Ratio of Sub- lingual to Equally Effec- tive Subcu- taneous Dose	Criterion for Measuring Drug Effects
Cocaine.....	45.0	1.4	32	2	Excellent
Apomorphine.....	1.8	0.09	20	2	Emesis
Diacetylmorphine...	10.0	0.6	17	3	Tolerry fistula tracing
Strychnine.....	3.2	0.12	27	4	Convulsions
Thebaine.....	8.0	0.7	12	4+	Hyperexcitability
Emetine.....	10.0	1.1	9	6+	Emesis
Atropine.....	14.0	1.8	8	8	Tolerry fistula tracing
Morphine.....	0.05	0.22	0.22	10	Tolerry fistula tracing
Dihydromorphinone	0.4	2.0	0.2	15	Tolerry fistula tracing
Codeine.....	16.0	8.0	2.0	15+	Tolerry fistula tracing

The effectiveness or ineffectiveness of this technic can be determined easily and, in fact, has been determined for many of the common drugs. The methods for establishing such data are simple but do involve more than the mere sublingual administration of drugs in their ordinary subcutaneous doses. Sublingual trials with minimally effective doses do not ordinarily permit positive conclusions, and this is the sort of experimentation which has led to the numerous unreliable impressions which have been reported from time to time. This is particularly true if the only criterion of effects is the comment of patients regarding their subjective sensations. To be certain that a drug is not effective by sublingual administration it might be considered necessary that it be administered in doses several times larger than the minimally effective subcutaneous dose. If, for instance, atropine is ineffective in successive trials with increasing sublingual doses up

to 10.0 mg., it can be safely accepted that atropine in ordinary doses (0.5 to 1.0 mg.) is not effective by sublingual application. This sort of experiment might involve some hazard for the human subject, but the hazard actually can be reduced to slight significance by a process of cautiously increasing the doses through successive trials after starting with the ordinary subcutaneous doses. Additionally a method of preliminary animal experimentation is available which has proved to be a reliable guide. Dogs can be managed in such a way as to avoid or minimize swallowing and, as a further method of proof for those few drugs which are well absorbed, dogs can be used after esophageal operations which completely exclude the possibility of swallowed drugs passing into the stomach or intestine. Also in dogs, fistula, tone changes, blood pressure changes, anesthesia, excitation and other methods can be used as a suitable means of bioassaying the extent of drug absorption. Without exception, drugs are more readily absorbed from the sublingual area of the dog than from the same area in man. Hence a drug which does not penetrate the mucosa of a dog can be applied experimentally to the mucosa of human subjects in relatively large doses with assurance that effects will not be obtained.

In the course of experimentation it has been found that the penetration of drugs through the oral mucosa is strictly a selective process. Some few drugs penetrate readily and can be practically administered in this way, others penetrate only when larger doses are applied, while others seem to be almost incapable of any significant degree of penetration. The most important determining factor is the fat-water distribution coefficient. The penetrability of drugs is so conditioned by this simple physicochemical constant that their penetrability may be predicted with fair accuracy in advance of any biologic tests. This is particularly true within a given group of chemically related drugs as, for instance, the group of alkaloids. The accompanying table gives data of this sort for a number of the common alkaloids.⁵ Penetrability, as here determined in dogs, is expressed as the ratio:

$$\frac{\text{Dose producing definite effect}}{\text{Dose producing same effect}}$$

This ratio can be taken as a reasonably satisfactory expression of the ability of a drug to penetrate the oral mucosa; the smaller the factor, the greater the penetrability.

The correlation in the table shows irregularities, and this might naturally be expected from the type of experiments involved. There are obviously several other factors than the one correlated here. The absolute doses, the degree of irritation, the production of salivation, vasoconstrictor effects and other factors are capable of affecting the absorption behavior. With apomorphine and cocaine, for instance, there is a wide disparity of absolute dose in these experiments. This also affects the comparison of codeine and dihydromorphine. With strychnine the intense bitterness no doubt adversely affects its absorption results. Even with this necessary disparity of conditions, the table demonstrates a significant trend which is sufficiently valid to distinguish those drugs which are incapable of practical sublingual administration from those which may possibly be given by this route.

A number of the more common drugs can be considered individually and their absorption behavior explained on the basis of this correlation. The following summary is based chiefly on a review of the literature but also includes a number of unpublished observations.

DRUGS WHICH PENETRATE READILY

Organic Nitrates.—Glyceryl trinitrate is the one drug whose absorption by sublingual application has been undisputed over the several decades it has been effectively used in this way. Ample documentary evidence for its absorption has been furnished by Grossmann and Sandor⁶ and by Evans and Hoyle.⁷ Its relatively high solubility in fats (100 mg. per cubic centimeter) is clearly based on its chemical similarity to fats, since it is a triester of glycerin. Its distribution coefficient is exceptionally high, Krantz and his co-workers⁸ reporting it as 1,820.

Erythrityl tetranitrate, being simply a higher homologue of the preceding, has essentially the same type of solubility characteristics. Krantz and his associates report its fat-water distribution coefficient as 290. Its penetrability through the oral mucosa has been demonstrated in human subjects by determinations of blood pressure, observations of face flushing and subjective sensations of head fullness, weakness and headache. Since the blood pressure changes with this drug are very moderate, it is considered that the other criteria are more significant. Eighteen trials in 8 human subjects with doses of 32 to 64 mg. have demonstrated the validity of this method of administration.⁹

Steroid Hormones.—Adequate demonstrations have shown the effectiveness of some of the steroid hormones by this method of administration. This is a development of the past few years and might have been anticipated from the recognized fat solubility of these compounds. Numerous observations, further, have demonstrated the effectiveness of these drugs by percutaneous administration. The range of fat-water distribution coefficient for the various steroid hormones is in the neighborhood of 40 to 2,000 according to data supplied by the Ciba Pharmaceutical Products, Inc.

Androgens.—Testosterone compounds, used in solutions of propylene glycol or in specially prepared compressed tablets, have been shown to be effective by sublingual application.¹⁰ Spence,¹¹ treating a surgical castrate, found that about 10 mg. of methyl testosterone sublingually was equal to 15 mg. swallowed. He considered the sublingual dose of methyl testosterone to be about four times the dose of testosterone propionate intramuscularly. Lissner, Escamilla and Curtis,¹² using propylene glycol solutions of these androgens sublingually, successfully treated 5 typical eunuchoids who

had received previous therapy and 4 previously untreated hypogonadal patients. A solution containing 25 mg. per cubic centimeter was used and total daily doses of 10 to 25 mg. administered. Striking objective and subjective benefits were obtained. In some cases the sublingual effective dose was one-third the similarly effective oral dose, in some cases one-half as much as the oral dose was required and in other cases about as much was required sublingually as orally. The oral dose was considered about twice the intramuscular dose. Sublingually, free testosterone was more effective than either methyl testosterone or testosterone propionate. Lissner and Curtis¹³ subsequently extended these studies to include 12 cases of male hypogonadism and considered that compressed tablets containing 5 mg. each of methyl testosterone were more satisfactory than the propylene glycol solutions.

Salmon and his associates¹⁴ and Joel¹⁵ used androgens sublingually in the management of various gynecologic disorders. Joel described the treatment of 19 such patients, to whom he administered 5 to 30 mg. of methyl testosterone daily. One patient received 900 mg. sublingually in one month and evidenced mild arrhenomimetic effects.

Estrogens.—Miescher and Gasche¹⁶ showed in castrated female rats that estradiol was ten to twenty times more effective sublingually than orally. Numerous observers have reported the clinical effectiveness of various sublingually administered estrogens.¹⁷ Hall¹⁸ and Salmon and Geist¹⁹ showed clinically that α -estradiol in propylene glycol by this route produced typical cornification in the vaginal smear. Salmon and Geist administered daily doses of 0.2 to 0.3 mg. of α -estradiol to 8 patients and at the end of one week showed definite estrogenic effects by vaginal smears and biopsies in all. Hall used a solution containing 0.5 mg. per cubic centimeter in a series of about ninety-eight menopausal types of patients. He considered the sublingual doses about equal to injected doses milligram for milligram.

Endometrial proliferation has been artificially produced in patients by the sublingual administration of α -estradiol. Herrnberger²⁰ and Giesen²¹ obtained these effects with total doses of about 180 mg. Joel,²² however, using a specially prepared tablet, reported similar effects with total doses of only 60 to 90 mg. of α -estradiol. Herrnberger reported that 450 mg. orally ingested would not produce these results. Joel also reported 27 miscellaneous gynecologic cases treated by sublingual α -estradiol and considered that

two to three times as much was required by the sublingual route as when estradiol propionate was injected intramuscularly.

Castrodale, Loeffel and MacBryde²³ administered diethylstilbestrol in propylene glycol to 17 women suffering from typical symptoms of estrogen deficiency. A solution containing 20 mg. per cubic centimeter was used and results were judged by relief of symptoms and changes in vaginal smears. All patients were treated for a month or more. Results indicated that the sublingual doses are about equally effective as swallowed doses and half as effective as intramuscular doses.

Anhydrohydroxyprogesterone.—Joel reported that sublingual total doses of 150 mg. of anhydrohydroxyprogesterone produced transformation of the endometrium toward the secretory phase. This he contrasted with oral doses of about 220 to 300 mg. which were required to produce the same effect. The latter oral doses were considered to be five to eight times the injected dose.

Desoxycorticosterone Acetate.—Anderson, Haymaker and Henderson²⁴ administered desoxycorticosterone acetate sublingually to 6 patients with Addison's disease. They used a propylene glycol solution containing 10 mg. per cubic centimeter and administered 2 to 6 mg. daily in divided doses. All patients were reported in excellent condition after six to eight weeks

Fig. 1.—Stomach contractions in dog. Recorded by balloon inserted through gastrostomy opening. Apomorphine hydrochloride (0.1 mg. per kilogram) administered sublingually. Retching (R) in two minutes, vomiting (V) in five minutes. Dogs do not usually vomit with ten times this dose by stomach tube.

of such treatment. They considered this method to be quantitatively as effective as the intramuscular or subcutaneous injections of oil solutions of desoxycorticosterone acetate, which had been previously administered to 5 of the 6 patients. They do not consider the oral ingestion of this drug to be satisfactory even when ten times the usual doses are given. Turnoff and Rowntree²⁵ confirmed the satisfactory management of 2 cases of Addison's disease by this same method.

Similarly, Heni²⁶ treated 3 cases successfully and considered that the sublingual dose must be one-third greater than the intramuscular dose. Dunlop,²⁷ working with 7 cases, obtained satisfactory results by application of the drug to the oral mucosa but considered that three to five times as much was required as by the intramuscular route. The use of compressed tablets applied "sublabially" was considered most effective. Wilson²⁸ used propylene glycol solutions in 4

cases and obtained evidence of absorption but not to a degree which was considered satisfactory.

Anderson and Haymaker²⁹ subsequently found it advisable to add up to 20 per cent of alcohol to the solution they had been using. They reported then the management of 17 cases of Addison's disease with this improved solution. Thorn and his associates³⁰ similarly demonstrated the effectiveness of the sublingual route by determinations of sodium chloride excretion. They considered that the sublingual dose is about three to four times that by injection, although Anderson and Haymaker,²⁹ in reviewing their report, insist that with certain precautions the ratio is lower and certainly not more than two to one.

Vitamins.—The fat soluble vitamins no doubt could be administered by sublingual application, although there is ordinarily no need for administration by this route. The effective administration of some of these products by percutaneous application can be taken to demonstrate a high degree of penetrability, although these conditions have important differences. Vitamin A,³¹ vitamin D³² and vitamin K³³ preparations have been shown recently to be effective by percutaneous application.

Alkaloids.—Apomorphine, although very slightly soluble in fats, is extremely insoluble in water, with the result that its distribution coefficient is relatively high.⁵ Its penetration through the oral mucosa of the dog is good, and consistently effective sublingual doses are only twice the subcutaneous doses. There is no possibility that swallowing explains these effects, since approximately ten times as much as the subcutaneous dose is necessary if the drug is given by stomach tube. The high degree of absorption of apomorphine through other mucosae has been described by Macht.³⁴ When administered to human subjects by sublingual application, doses of 6.5 to 10 mg. produced moderate to intense nausea and depression in six of eight trials.³⁵ It is evident that this drug can be effectively administered sublingually if doses about twice the subcutaneous dose are used. The circumstances, however, would be exceptional under which the sublingual application of apomorphine could prove practically useful.

Nicotine passes through the oral mucosa with considerable ease and promptness, which is chiefly a point of toxicologic interest. Franke and Thomas³⁶ have shown that the minimum fatal sublingual dose in unanesthetized dogs is 10 mg. per kilogram, which is only about three times the minimum fatal dose by intravenous injection. The oral use of tobacco products as an indulgence undoubtedly involves some direct absorption of nicotine through the buccal mucosa. Nicotine is something of an exception to the proposed correlation, since its fat-water distribution coefficient

is low (2.6). It is, however, completely miscible with fat in all proportions, and its behavior may thus be considered more as a modification of the correlation than as a contradiction. Thus, to state the correlation more completely, it could be said that the penetrability of drugs through the oral mucosa is favored by a high fat-water distribution coefficient or an exceptionally high fat solubility.³⁷ In addition to the unique solubility of nicotine in fats, this alkaloid is unusually alkaline and irritant. The latter feature is possibly an important conditioning factor in its high degree of penetrability.

Cocaine is another drug whose absorption through the buccal mucosa is chiefly a matter of toxicologic interest. Its distribution coefficient is relatively high (32), and in dogs excitement effects can be produced by sublingual doses which are only twice the subcutaneous dose.³⁸ In human subjects the absorption of cocaine through the more permeable nasal mucosa is well known.

DRUGS WHICH DO NOT PENETRATE THE ORAL MUCOSA IN ANY PRACTICAL DOSAGE

Of the very considerable number of drugs which are nonirritant and which are effective in small doses, most have been claimed at various times to be effective by sublingual application.¹ It may be accepted, however, that if they do not exhibit a high distribution coefficient or a high fat solubility they are not effectively administered in this way, and any effects which may have been obtained in this way are due to small amounts having been swallowed.

Morphine Derivatives.—Morphine, codeine and dilaudid have low distribution coefficients (less than 2) and are very slightly soluble in oil. From observations with trained Thierry fistula dogs it has been demonstrated that they do not pass through the oral mucosa to any significant degree. In dogs, sublingual doses ten or more times greater than the subcutaneous doses were necessary in order to obtain typical effects. (With these three drugs, by sublingual, stomach tube and subcutaneous routes, tracings were obtained, each following a preliminary control period of regular peristaltic waves.³⁴ I consider the latter type of control more or less obligatory when Thierry fistula tracings are made for the purpose of semiquantitative evaluation.³⁷ In human subjects sublingual doses were successively increased to 120 mg. with morphine and to 15 mg. for dilaudid. No subjective effects were obtained from these sublingual doses, although these doses were ten or more times greater than trial subcutaneous doses which produced recognizable subjective effects.

According to the correlation of the table it is evident that diacetyl morphine is the only morphine derivative in this group which might reasonably be expected to be effective by this sublingual route. It is a diester and hence more related to typical fats than the other derivatives and, as expected, has a higher distribution coefficient (17). Its sublingual absorption in dogs supports the correlation, and consistent effects were obtained with doses only three to four times greater than the subcutaneous dose (conclusion based on tracings with Thierry fistula dogs).³⁸ Suggestive but inconsistent effects were obtained in human trials with

sublingual doses up to 15 mg. Definite subjective and objective effects (stomach spasm as shown by balloon tracings) were obtained with 1.5 to 4 mg. subcutaneous doses in some of the same subjects. Since this is the only morphine derivative which has even suggestive possibilities of practical administration in this way, further experiments were directed toward methods which might increase penetrability. A number of trials were made in Thierry fistula dogs using 40 per cent alcoholic solutions of the drug. No significant increase in penetrability was noted. Similar solutions in human subjects did not produce definite effects in doses up to 25 mg. Mixtures made up with bile salts did not give consistent or definite effects in doses of 10 mg. to 15 mg. Mixtures made up with 7 parts of propylene glycol and 3 parts of an aqueous solution of 2 to 10 per cent sodium carbonate gave inconsistent and only slightly suggestive subjective effects in doses of 15 mg. With the latter dose mixture, fourteen trials were made in 11 subjects.³⁹

The conclusion stands clearly that these opiates cannot be administered sublingually by any of the currently used technics. That member of these four morphine derivatives, diacetyl morphine, which by *in vitro* and by animal experiments clearly indicated the

Fig. 2.—Thierry fistula tracings each from same dog: Top, diacetyl-morphine hydrochloride (0.1 mg. per kilogram) subcutaneously; moderate stimulation. Middle, ditto with 0.4 mg. per kilogram subcutaneously; pronounced effect. Bottom, ditto with 0.4 mg. per kilogram sublingually; effect comparable to that with 0.1 mg. per kilogram subcutaneously.

highest degree of penetrability, was not satisfactorily effective in human subjects with relatively extreme doses, and in special mixtures which in some cases were too irritant for ordinary use.

Ergot Alkaloids.—Ergonovine has characteristics which make it a good test of the validity of the correlation. By other counts it should be well suited for sublingual administration; it is effective in very small doses (0.2 mg.), it is known to be absorbed exceptionally well after swallowing, its salts are highly water soluble and such concentrated solutions can be administered without irritation. Its distribution coefficient, however, is very low and, in agreement with the correlation, our observations show it to be ineffective by sublingual application.

Pressure tracings made with balloons in uterine fistulas of dogs have shown that large sublingual doses were ineffective under conditions in which one-fifth the same doses subcutaneously produced definite effects. In human male subjects nine trials in 4 persons with doses from 0.5 to 2.5 mg. of ergonovine maleate produced no more than barely recognizable subjective sensations in 1 or 2 instances.³⁹ This is in contrast to a clinical series with ergonovine intravenously in

104 patients, 50 per cent of whom were nauseated and 18 per cent of whom vomited.¹⁰ Subcutaneous doses of the amount used in our sublingual trials cause intense nausea, tingling in the extremities, cerebral excitation and precordial oppression.

In some of the earlier clinical experiments with ergonovine¹¹ results were reported which indicated the effectiveness of its sublingual administration and, in

fact, it has been an occasional practice to administer it in this way in some of the larger obstetric clinics of this country. I cannot reconcile this practice with our observations and suggest that the clinical results must have been due to swallowing

Fig. 3.—Uterine contractions in 15 Kg. dog under pentobarbital light anesthesia. Ergonovine maleate in sublingual dose of 0.4 mg. per kilogram has no effect, while subsequent subcutaneous administration of same dose produces definite stimulation.

Ergotamine exhibits an indicated distribution coefficient which puts it in the borderline group deserving a trial by the sublingual method. The need for its repeated administration in the management of some migraine cases makes this technic an attractive one. The limited water solubility of its salts, however, makes it difficult to administer enough to be effective by this route. Kelly¹² concluded from experiments on himself that two tablets of ergotamine sublingually were equal to five or six orally. Von Storch,¹³ working with a number of migraine patients, found it necessary to give six to eight times as much by sublingual as by subcutaneous administration. If a sufficiently water soluble salt of ergotamine should be developed, it might possibly be given routinely in this way.

Autonomic Drugs.—With atropine, in vitro and animal observations indicate a low degree of penetrability. Definite effects in human subjects were obtained only after the dose had been increased to a degree which would have been dangerous if the drug was swallowed (12 to 15 mg.). Such effects as are obtained with these larger doses may be attributed to possible swallowing of a small fraction of the drug. It is conceivable that, among the various synthetic and natural products which have pharmacologic similarity to atropine, some may be found which have an adequate degree of penetrability. No systematic study of this sort has been made. Wallgren¹⁴ has reported the effective lingual application of eumydrin in the management of congenital pyloric stenosis. His results were probably due to the drug being swallowed.

Mecholin has been shown to produce typical effects (salivation, defecation, miosis) in dogs by sublingual application but only in doses considerably larger than the subcutaneous dose producing the same effects. Relatively large doses (up to 400 mg.) had no effect when administered sublingually to human subjects.

Barbiturates.—The sodium salts of two barbiturates, pentobarbital³⁵ and 1-methyl-butyl methallyl barbiturate⁹ have been shown to produce surgical anesthesia in dogs by sublingual application. These anesthetic effects, involving a total of fifty-five experiments, were obtained more rapidly by sublingual application than by stomach tube administration, and these anesthetic effects were also obtained equally well in dogs with esophageal fistulas. This necessitated the passage of considerable quantities of drug through the oral mucosa. In the case of pentobarbital at least 250 mg. passed directly through the mucosa of a 10 Kg. dog, since this is the minimum dose producing anesthesia by intravenous injection. Despite these demonstrations of the direct passage of impressively large quantities through the oral mucosa, it is not considered practical to administer these drugs by this method. The penetration obtained in dogs was undoubtedly due in a large measure to the irritant action of these alkaline sodium salts. In human trials, sedative effects were obtained only with 250 mg. doses of sodium pentobarbital and, this involved an unacceptable degree of mucosal irritation.

Analeptics.—Strychnine and picrotoxin both produced convulsions in dogs when simply applied to the oral mucosa. The picrotoxin was administered in mixtures of alcohol or propylene glycol with water. On the basis of one hundred and three experiments in dogs it has been concluded that the sublingual/subcutaneous ratio of effective doses is four for strychnine and six for picrotoxin.⁴⁵ This indicates that dangerously large doses would be needed in order to obtain penetration of effective doses through the oral mucosae of human subjects. Epinephrine by sublingual application in dogs does not produce effects in doses two hundred and fifty times greater than the intravenous dose producing recognizable effects (depression of motor activity of intestinal fistulas). In human subjects, sublingual doses of 3 mg. were without effect although the same subjects showed definite responses to one-tenth that amount by subcutaneous injection.³⁵ A recent statement⁴⁶ that asthmatic infants respond to

Fig. 4.—Thierry fistula tracing (continuous). Epinephrine in doses of 0.05 mg. and 0.10 mg. intravenously produces brief but definite depression of intestinal activity. Dose of 3.0 mg. sublingually during interval between injections does not produce recognizable depression.

sublingual doses of 1.5 mg. of epinephrine is interesting since it is possible that penetration is more easily obtained in infants. The difference, however, would have to be very great in order to reconcile this statement with the observations that I have made. Ephedrine exhibits more promising solubility characteristics than epinephrine, but a limited number of experiments

with dogs and with human subjects showed that its degree of penetration was low.

Metrazol and hydrocyanic acid can be shown to produce their typical effects in dogs by sublingual administration, but the degree of penetrability is not striking and no effects were obtained in human subjects with relatively large doses. Kuschel⁴⁷ demonstrated perlingual absorption of metrazol in cats. The required doses, however, were of about the same order as my associates and I found in dogs.

Cardiac Glucosides.—Since the cardiac glucosides are effective in very small doses they might be considered suitable for this type of administration, and some writers have claimed this to be the case. The solubility characteristics, however, are clearly unfavorable and a very conclusive study by Eggleston and White⁴⁸ has demonstrated the lack of penetrability of amorphous strophanthin. These observers applied relatively large doses of an alcohol solution of strophanthin to the oral mucosa of 18 patients with cardiac decompensation. No effects were obtained, although subsequent administration of digitalis in the usual way was followed by definite and typical effects. Digitoxin has somewhat better promise based on solubility characteristics, but a few preliminary trials of its alcoholic solution in dogs indicated to us that it would not be effective sublingually in any practical dosage.

Insulin is protein in character and hence would not be expected to exhibit favorable oil solubility. In dogs, no effects were obtained by sublingual application of doses twenty times greater than those which produced pronounced hypoglycemia by subcutaneous injection.⁴⁹ McCullagh and Lewis⁴⁹ also found that the sublingual technic was ineffective in dogs. They further demonstrated the ineffectiveness of the sublingual technic in 4 human subjects, including 1 who was diabetic. Their observations satisfactorily refute the several unimpressive reports which have claimed the successful sublingual administration of insulin.⁵⁰

COMMENT

These observations show that the fat-water distribution coefficient of drugs is a dominant factor in determining their penetrability through the oral mucosa.

With the drugs so far studied, coefficients of approximately 20 to 30 fall in the borderline range of effective administration by sublingual application. A number of the common drugs with lower coefficients have been shown to be ineffective by sublingual application. Some of the organic nitrates and the steroid hormones have been effectively administered sublingually, and their coefficients fall in the range of 40 to 2,000. This may be considered an optimum range. It is probable that drugs with coefficients higher than this range may not be effective, in which case the explanation would be that adequate concentrations could not be obtained in the aqueous salivary fluids of the mouth.

In the table the solubilities are those of the free alkaloids or bases, while the measurements of penetrability were made with soluble salts of the alkaloids. Since the correlation set up in this way is clearly a

valid one, it may be concluded that the salt dissociates and allows the free base to act in the mouth as it does in the in vitro oil-water system. Apparently, in the mouth, the same conditions of competition of solvents prevails and, in this case, the predominant competition is that between the aqueous salivary fluids and the fat in the protoplasm of the cells. The solubilities of the alkaloidal salts seem to have no significance in this problem beyond the need for enough water solubility that a reasonably concentrated water solution can be administered.

Experimentally, it was found that there was no special penetrability to be obtained by using the free alkaloid rather than the soluble salts. To use the free alkaloid, solutions in water and alcohol or in water and propylene glycol were employed. The further admixture with alkalis and with surface active agents such as bile salts provided no significant improvement in penetrability. Some have suggested that the different areas of the buccal mucosa should be studied to determine differences in penetrability. It is doubtful, however, that this will lead to any improved technic, since we found, at least, no advantage in perlingual over sublingual application.

The most feasible method for improving the sublingual penetrability of a given drug seems to be the preparation of chemical derivatives with more favorable solubility characteristics. Nitrate and acetate esters, for instance, will exhibit a significantly improved distribution coefficient, and in some cases the typical activity of the original drug can be retained or even intensified. This procedure would be most applicable in the case of those drugs which are on the borderline of effective penetrability. It is suggested here that in the synthetic preparation of new drugs and in the chemical variations of the standard drugs this particular feature might be advantageously added to other objectives.

SUMMARY AND CONCLUSIONS

The sublingual administration of drugs is a simple and, at times, an advantageous technic for those few drugs with an adequate degree of penetrability. The majority of drugs, however, do not penetrate the oral mucosa in significant amounts, and it is unsound practice to rely on this technic with any drug whose effectiveness by this route has not been conclusively demonstrated.

A simple in vitro correlation, depending on solubility characteristics, largely determines the ability of drugs to penetrate the oral mucosa. As new drugs are developed, it is suggested that those which give promise according to this criterion be subjected to adequate trial by absorption experiments in animals and human subjects.

Orthopedics.—The word orthopaedic was compounded in 1741 by the Parisian physician Nicolas André from the Greek roots *orthos*, meaning straight, and *païs*, meaning child. He used it in a treatise on skeletal deformities which he attributed to muscle imbalances during childhood. The word has survived, while André's theory has long since been discarded. Today the word has a quite different meaning. Orthopedics is the branch of medicine that deals with diseases and injuries of bones and joints, including deformities, both congenital and acquired, fractures and dislocations. The orthopedist is a surgeon rather than a physician prescribing corrective exercises as André had intended.—Haagensen, C. D., and Lloyd, Wyndham E. B.: *A Hundred Years of Medicine*, New York, Sheridan House, Inc., 1943.

COMBINED PENICILLIN AND HEPARIN THERAPY OF SUBACUTE BAC- TERIAL ENDOCARDITIS

REPORT OF SEVEN CONSECUTIVE SUCCESSFULLY
TREATED PATIENTS

LEO LOEWE, M.D.
PHILIP ROSENBLATT, M.D.
HARRY J. GREENE, M.D.
AND
MORTIMER RUSSELL
BROOKLYN

In experimental thrombotic bacterial endocarditis¹ the disappearance of vegetations requires the use of a suitable chemotherapeutic agent and an anticoagulant. The clinical application of this principle in subacute bacterial endocarditis has been disappointing; the techniques of therapy are cumbersome, the toxicity of treatment has been excessive even for an otherwise fatal disease and the successes have been few and irregular.² Early efforts made with sulfonamides, with or without heparin, have been mostly abandoned. The introduction of penicillin proved equally disappointing; the commission appointed by the National Research Council has already reported unfavorably and discouraged the use of the at present inadequate supply of the drug for the treatment of viridans endocarditis.³

The present report, which deals with the apparently successful treatment of 7 consecutive examples of subacute bacterial endocarditis, employs variations on previous techniques. Penicillin⁴ is used to replace sulfonamide in the conjoint chemotherapeutic-anticoagulant attack and prolonged heparinization⁵ has been accomplished primarily by a special method devised for the subcutaneous deposition of the drug.⁶

CLINICAL MATERIAL

Six of the 7 patients⁷ suffered from a bacterial endocarditis that was engrafted on a chronic rheumatic valvulitis, and the other had a congenital cardiac defect. In 5 of the 7 patients the etiologic organism was a *Streptococcus viridans*; the sixth patient had a hemolytic streptococcus and the seventh a pneumococcus type 27.

TECHNIC OF TREATMENT

Probatory sensitivity tests were performed in each instance. The bacteria were inhibited within the dilution of 0.007 to 0.01 Florey units per cubic centimeter of penicillin. The daily dosage of penicillin varied from

40,000 to 200,000 Florey units and the total ranged from 867,920 to 7,890,340 Florey units. The heparin dosage approximated 300 mg. every second day when given subcutaneously and 200 mg. daily when incorporated in the venoclysis.

Heparinization was checked by the Lee-White modification of Howell's method for determining blood coagulation time.⁸ A reading of thirty to sixty minutes was regarded as satisfactory evidence of anticoagulant activity. The present technic has minimal toxicity; it is simple of accomplishment and the immediate results, at least, appear to be uniformly successful.

CASE REVIEWS

CASE 1.—Subacute bacterial endocarditis, pneumococcus type 27, ten weeks; congenital cardiac anomaly (septal defect); post-therapy, five months, clinically well and blood stream sterile.

I. Z., a girl aged 7½, was admitted to the Jewish Hospital of Brooklyn on June 3, 1943 because of chills and fever of ten weeks' duration. At the age of 9 months a loud precordial murmur was found on routine physical examination. Three years before admission she had a bout of unexplained fever lasting eight weeks. She remained perfectly well thereafter until ten weeks before admission, when she developed an

Chart 1.—Temperature and dosage in case 1.

earache and low grade fever lasting three days. Two days after this subsided she suddenly developed a high temperature, which was spiking in character and continuous to the time of admission. She also had intermittent chills. Four weeks prior to hospitalization she developed lobar consolidation (infarct?) which persisted ten days. She lost 13 pounds (6 Kg.) in the last ten days.

On admission the temperature was 103.8 F., pulse 132 and respirations 32. Blood pressure was 110/90. The heart was slightly enlarged to the left, and a loud systolic murmur was heard all over the precordium. The spleen was just palpable on inspiration. The clinical impression was subacute bacterial endocarditis engrafted on a congenital cardiac anomaly (septal defect). Blood culture, taken on June 4, revealed pneumococcus, type 27. Massive sulfonamide therapy⁹ was begun June 4, consisting of 10 Gm. of sodium sulfadiazine, 15 Gm. of urea and 500 mg. of ascorbic acid dissolved in 650 cc. of distilled water administered by venoclysis. Six such courses were given over a period of twelve days without improvement. Blood cultures taken on June 9, 14 and 18 remained positive for pneumococcus type 27. Sulfadiazine blood levels ranged up to 78.8 mg. per hundred cubic centimeters total and 74.2 mg. per hundred cubic centimeters free. In view of the lack of response to this therapy, a combined penicillin-heparin regimen was initiated June 19. The patient received subcutaneous

deposits of 100 or 200 mg. of heparin approximately every other day. During the first twenty-four hours, 42,400 Florey units of penicillin dissolved in 2,000 cc. of 5 per cent dextrose in saline solution was given intravenously by slow drip. On June 20 and 21 42,400 and 129,600 units respectively were administered by vein. The venoclysis was then discontinued because the patient became extremely uncooperative. Blood culture on June 21 showed no growth. Although her general condition was good the temperature persisted and it was decided to resume penicillin therapy by the intramuscular route. On June 24 penicillin was again started with 64,800 Florey units in fractional intramuscular dosage. Combined penicillin-heparin therapy was then continued without interruption until July 5, a total of 867,920 units of penicillin and 1,200 mg. heparin being given over a period of sixteen days. On June 27 her temperature, although still elevated, was on a lower level. On June 29 she showed evidence of extensive infarction of the lower two thirds of the right lung. Blood cultures taken on June 28, July 6 and July 19 were sterile. On July 22 her general condition was good, a slight elevation of temperature to about 100 F. being ascribed to a cold which she developed. She was discharged July 23 for further convalescence at home. Since then she has been seen periodically, her temperature remaining normal and the blood cultures negative. She is now attending school regularly.

CASE 2.—*Subacute bacterial endocarditis, Streptococcus viridans, ten months; chronic rheumatic cardiovalvular disease, aortic; no response to massive sulfonamide and three courses of penicillin-heparin therapy; fourth course of penicillin-heparin therapy successfully sterilized blood stream; clinically much improved.*

S. R., a man aged 34, was referred to the Jewish Hospital of Brooklyn by Dr. I. L. Epstein on Feb. 7, 1943 complaining of fever and cough of six weeks' duration. At the age of 13 he had spent two months in bed because of "an inflamed heart chamber" and joint pains. At the time a diagnosis was made of rheumatic heart disease. The patient was well until about six weeks before admission, when he developed a cough followed by persistent low grade fever, which continued despite oral sulfadiazine. There were no physical signs apart from a systolic murmur at the mitral area and a diastolic murmur at the aortic area. The admission diagnosis of subacute bacterial endocarditis was confirmed by blood cultures taken February 10 and 12, both of which were positive for *Streptococcus viridans*. On February 22 he was given 18 Gm. of sodium sulfapyridine by intravenous drip, which failed to sterilize the blood stream. Supplemental fever therapy through the medium of intravenous triple typhoid vaccine was instituted March 8. Sulfadiazine levels were maintained around 20 mg. per hundred cubic centimeters, and fever treatments were

levels reached as high as 123 mg. per hundred cubic centimeters total and 109 mg. per hundred cubic centimeters of free sulfadiazine. Despite nineteen such intensive courses of treatment over a period of six weeks the blood cultures on May 22 and on June 9 and 16 were richly positive. On June 19 a three day course of penicillin-heparin therapy was initiated, which was obviously inadequate. When additional penicillin supplies were available on June 27 the patient was started

on a nine day schedule comprising approximately 40,000 units of penicillin daily by vein and 300 mg. of heparin deposited every other day under the skin. When the blood cultures remained positive, massive sulfonamide therapy was again projected. From July 7 to August 17 he received variously sodium sulfadiazine, sodium sulfapyridine, sodium sulfathiazole

Chart 3.—Remainder of course in case 2.

and sodium sulfamerazine without sterilization of the blood stream. On August 27 a more elaborate course of penicillin-heparin therapy was begun with 200,000 units of penicillin daily by venoclysis and 300 mg. of heparin subcutaneously approximately every other day. This was continued for fourteen days, after which the blood cultures remained negative until October 4, when organisms reappeared. The temperature, which had been flat for weeks (charts 2 and 3) now showed some irregularity, and on October 9 a fourth course of penicillin-heparin was initiated. The daily dosage plan consisted of 200,000 units of penicillin and 200 mg. of heparin given together by continuous venoclysis for a period of twenty-four days. The occasional sharp febrile rises due to heparin receded promptly following temporary withdrawal of the drug. Since completion of the therapeutic program the temperature has remained normal with the exception of a slight fever due to a complicating nasopharyngitis. The blood cultures since October 13 have been sterile; the sedimentation rate receded from a high of 130 mm. per hour on June 14 to 10 mm. per hour on November 26 and the patient is in excellent condition. In all, this patient received four courses of combined therapy totaling 7,890,340 Florey units of penicillin and 7,100 mg. of heparin.

CASE 3.—*Subacute bacterial endocarditis, Streptococcus viridans, eight months; chronic rheumatic cardiovalvular disease, mitral and aortic; three cycles of penicillin-heparin therapy; no clinical or laboratory evidence of bacterial activity for four months.*

L. O., a woman aged 24, unmarried, was admitted to the Jewish Hospital of Brooklyn on April 16, 1943. Her first attack of rheumatic fever, of which she had three or four, occurred at the age of 7. Her present illness began in December 1942 with complaints of chills, fever, malaise, pain in the hip and occasional crops of petechiae on the arms. She did not improve with home care and finally entered the Mount Sinai Hospital of Cleveland, where the diagnosis of subacute bacterial endocarditis due to *Streptococcus viridans* was established. This diagnosis was substantiated, clinically and bacteriologically, at the Jewish Hospital. A rough systolic thrill over the aortic area and systolic and diastolic murmurs, loudest at the base, indicated a predominant aortic valve lesion. There were several petechiae on the fingers. The spleen was not palpable. The patient's condition did not change materially following intensive oral and parenteral administration of sulfadiazine, which achieved blood levels of 41.2 mg. per hundred cubic centimeters total and 37.0 mg. per hundred cubic centimeters free. Fresh petechiae appeared occasionally, and the temperature swung irregularly up to 103 F. From May 17 until July 31, when the penicillin-heparin program was started she received fifteen courses of sulfadiazine, each treatment comprising 10 to 20 Gm. of sodium sulfadiazine, 15 to 30 Gm.

Chart 2.—First twenty-eight weeks in case 2

given approximately every other day. After three such pyrexia reactions heparin was added to the program. However, on March 23 and April 5 and 14 *Streptococcus viridans* was recovered from the blood stream despite adequate fever therapy and intensive sulfadiazine medication, which had attained blood levels up to 40 mg. per hundred cubic centimeters. Sulfathiazole-fever therapy was similarly ineffectual. On May 4 massive cyclic intravenous chemotherapy was started with sodium sulfadiazine, the individual dose approaching 40 Gm. Urea and ascorbic acid were frequently employed as adjuvants. Blood

of urea and 0.5 to 1 Gm. of ascorbic acid given together by venoclysis. The complete lack of response, clinical and bacteriologic, to this massive chemotherapy justified the adoption of the penicillin-heparin regimen. The initial course of the latter lasted for nine days and consisted of 60,000 to 100,000 units of penicillin daily by continuous venoclysis and 100 or 200 mg. of heparin subcutaneously approximately every other

Chart 4.—First fifteen weeks in case 3.

day. The irregular temperature, up to 101 F. during therapy, was attributable in part to the heparin. Repeated blood cultures taken on August 9, 12, 16, 20 and 24 were all sterile.

When the patient continued subfebrile, however, additional treatment was projected. The dosage schedule of penicillin was 100,000 units daily for fourteen days. Collateral heparinization was started with 300 mg. and continued with 200 mg. subcutaneously every other day. On September 1 there was a definite febrile reaction which was due to a grossly contaminated penicillin solution. Although blood cultures taken August 28 and September 3 and 12 were reported sterile, the temperature, which had been normal, became slightly elevated to 100 F. A third course of penicillin and heparin seemed indicated and was begun on September 20, the penicillin dosage being increased to 200,000 units daily intravenously for twenty-eight consecutive days. Satisfactory heparinization was maintained with 200 mg. of heparin incorporated daily with the penicillin except when eliminated temporarily because of an inordinate febrile response or excessive anticoagulant activity.

Chart 5.—Sixteenth to thirty-second weeks in case 3.

Dental consultation¹⁰ on October 5 revealed the presence of advanced foci of infection and on October 13 several teeth were removed which were definitely diseased. Gauze packing saturated with penicillin solution, 5,000 units per cubic centimeter, was applied topically. *Streptococcus viridans* was recovered from the dental sockets.

10. The oral surgery on these patients was performed by Dr. M. D. Levin, attending oral surgeon of the Jewish Hospital.

The patient withstood the operative procedure well and all therapy was discontinued on October 19, five days after operation. Blood cultures taken on September 20 and 27, October 4, 12, 13, 18 and 25 and November 1 were all sterile and the temperature continued normal. The patient's weight has increased from a low of 71 pounds (32 Kg.) on July 10 to 92 pounds (42 Kg.). The patient received a total of 7,694,800 Florey units of penicillin in three cycles, 700,000, 1,400,000 and 5,594,800 units respectively. The overall total of heparin employed was 6,700 mg.

CASE 4.—Subacute bacterial endocarditis, *Streptococcus viridans*, three weeks; chronic rheumatic cardiovascular disease, mitral and aortic; post-therapy cerebral embolization with complete recovery; no clinical or laboratory evidence of bacterial activity, three months.

J. N., a man aged 31, was admitted to the Jewish Hospital of Brooklyn on Aug. 17, 1943 because of unexplained fever of three weeks' duration. He had rheumatic fever at the age of 6 and about ten to fifteen years ago noticed dyspnea on exertion, which has persisted to date. Three weeks prior to admission the patient developed pain, redness and tenderness of the toes of his right foot, followed in a week by fever and headache. Two days prior to hospitalization he experienced pain in the left upper quadrant. He suffered a weight loss of 5 pounds (2.3 Kg.).

On entrance his temperature was 98.2 F., pulse 120, respirations 24 and blood pressure 140/0. There were petechiae

Chart 6.—Course in case 4.

in the buccal mucosa. The heart was enlarged to the anterior axillary line. The first mitral sound was loud and snapping followed by a blowing systolic murmur; the second sound was blurred. There was a to and fro murmur at the aortic area transmitted to the neck, which obliterated the basal sounds. The spleen was palpable 3 fingerbreadths below the costal margin. The clinical impression was rheumatic heart disease with aortic stenosis and insufficiency, mitral insufficiency and subacute bacterial endocarditis with splenic infarction. Blood culture on the day of admission yielded 100 to 200 colonies of *Streptococcus viridans* per plate. On three separate occasions, August 19, 23 and 24, the patient was given intravenously by the gravity method 20 Gm. of sodium sulfadiazine, 30 Gm. of urea and 1 Gm. of ascorbic acid dissolved in 1,500 cc. of distilled water, all of which was wholly ineffectual. Furthermore, he reacted badly to this form of therapy, so that a penicillin-heparin regimen was instituted on August 26. The latter consisted of the daily administration of 100,000 Florey units of penicillin by continuous intravenous drip in conjunction with 300 mg. of heparin subcutaneously on alternate days. The temperature, which was irregularly elevated during the two weeks course of treatment, reached normal two days following its suspension. On September 14 the patient developed a complete left hemiplegia, which cleared entirely within four days. In view of the persistently negative blood cultures it was assumed that the embolization was abacterial. There were no further untoward events until his discharge on November 3, the temperature remained normal, the spleno-

megaly disappeared, the sedimentation rate fell from 95 mm. per hour on September 13 to 14 mm. per hour on October 18, and blood cultures done at practically weekly intervals up to and including October 25 were all sterile. His general condition at discharge was most satisfactory. His weight, which on admission was 145 pounds (66 Kg.), increased to 159 pounds (72 Kg.) on October 31.

As a precautionary measure a dental survey was done on October 19. Several foci of infection were found and the offending teeth removed. Ten thousand units of penicillin dissolved in 2 cc. of saline solution was injected intramuscularly every three hours on the day before, the day of and the day after the oral surgery. The operative site was packed with gauze dipped in 5 cc. of saline solution containing 20,000 units of penicillin. There was no febrile reaction, and the blood culture taken one hour after the dental extraction was sterile. *Streptococcus viridans* was recovered from cultures of the teeth.

In all, the patient received 1,400,000 Florey units of penicillin over a period of fourteen days, during which time he was also given 1,800 mg. of heparin.

CASE 5.—Subacute bacterial endocarditis, *Streptococcus viridans*, four months; chronic rheumatic cardiovascular disease, mitral; no response to intensive sulfonamide and initial course of penicillin-heparin therapy; second twenty-eight day cycle of penicillin-heparin therapy effected sterilization of blood stream and progressive clinical improvement, which has persisted two and a half months; possible penicillin-heparin sensitization.

C. M., a woman aged 22, married, was admitted to the Jewish Hospital of Brooklyn Aug. 17, 1943 because of "bacteria in the blood stream" of three months' duration. She had rheumatic fever at the ages of 6 and 9½ years, after which she was known to have a heart murmur. She was well until May 4, 1943, when she had the "grip," from which she recovered except for weakness and lethargy. About a week later she experienced sudden severe sacral and right lumbar pain, which was followed by ten days of hematuria. She subsequently had left upper quadrant pain which lasted one week. In the seventh week of her illness she was delivered of a 7 month infant under caudal anesthesia. Chills and fever recurred frequently, and blood cultures continued positive despite intensive sulfonamide therapy.

On admission the skin presented a pale lemon yellow pallor with a slight malar flush. There were no petechiae. The spleen was palpable 2 fingerbreadths below the costal margin. The heart was enlarged, and there was a rumbling to and

as the elevated temperature persisted and the blood culture on August 25 was positive. Accordingly penicillin-heparin therapy was started on August 26 with 100,000 units of the former daily by continuous venoclysis for fourteen days and 300 mg. of the latter subcutaneously approximately every other day. The temperature dropped with the onset of this regimen, ranging between 99.2 and 101 F. with the exception of an

Chart 8.—Course in case 6.

abrupt rise to 104 F. due to air borne contaminants in the penicillin solution. The rise in temperature on the day following suspension of the therapy was attributed to the heparin deposited the preceding day. In view of the continued irregular temperature despite the sterile blood cultures on September 12 and 17 following the positive one of September 10, additional penicillin-heparin therapy was projected. The daily dosage schedule begun on September 18 and continued uninterruptedly for twenty-eight days consisted of 200,000 Florey units of penicillin and 200 mg. of heparin given in combination by continuous intravenous drip. During the therapy the general condition of the patient was good in spite of irregular persistent elevation of temperature. A blood culture taken on October 4 was reported positive for *Enterococcus haemolyticus*, for which no valid explanation was forthcoming because the temperature was normal and the patient appeared exceptionally well. On the twentieth day of therapy, October 12, the temperature suddenly rose to 104 F. An occasional rale was heard at the left base and, on the premise that bronchopneumonia was developing, sulfadiazine 1.5 Gm. was administered every four hours. Blood culture taken this day was sterile, however, and with no further progress in the physical signs the temperature continued spiking daily for four days, attaining a level of 105 F. on the twenty-seventh day of therapy. Penicillin-heparin sensitization was suspected and all treatment stopped, following which the temperature promptly fell to normal within twenty-four hours and remained so thereafter. Blood cultures taken on October 18 and 25 and November 15 were sterile and the sedimentation rate dropped from 67 mm. per hour on September 13 to 12 mm. per hour on November 15. On October 27 two devitalized teeth were removed with the customary prophylactic penicillin treatment (see case 4). The patient was allowed out of bed on November 3 and discharged in excellent condition on November 17. Her weight increased from 105 pounds (48 Kg.) on September 12 to 120 pounds (54 Kg.) on November 14.

This patient received two courses of penicillin-heparin therapy, one of fourteen days' and the other of twenty-eight days' duration; the penicillin requirements were 1,400,000 and 5,250,000 Florey units respectively. The total of heparin employed was 7,600 mg.

CASE 6.—Subacute bacterial endocarditis, *Streptococcus haemolyticus*, three weeks; chronic rheumatic cardiovascular disease, aortic; widespread, almost lethal, embolizations; prompt, dramatic response to penicillin-heparin therapy; progressive clinical improvement and negative blood cultures, three months.

H. C., a woman aged 52, unmarried, was admitted to the Jewish Hospital of Brooklyn on Aug. 28, 1943 for penicillin-heparin therapy. She was transferred for this purpose from the St. Elizabeth Hospital of New York with a diagnosis of streptococcus (hemolytic) bacterial endocarditis engrafted on a chronic rheumatic cardiovascular defect. She entered the St. Elizabeth Hospital on August 7 because of pain in the

Chart 7.—Course in case 5.

fro murmur at the apex. There was a diastolic murmur at Erb's point. Blood culture taken on the day of admission revealed 250 to 350 colonies of *Streptococcus viridans* per plate. Chemotherapy was given by vein on August 8, 19, 23 and 24 in the form of sodium sulfadiazine 20 Gm., urea 30 Gm. and ascorbic acid 1 Gm. dissolved in 1,000 cc. of distilled water in combination with heparin. The latter was administered subcutaneously in 300 mg. doses. All this proved unavailing,

chest and upper abdomen, sudden weakness, general malaise and chills and fever of one day's duration. She was acutely ill and had two petechiae in the right conjunctival sac. The harsh systolic murmur over the aortic area and the diminished second aortic sound were indicative of an aortic stenotic lesion. The blood pressure was 104/60. *Streptococcus haemolyticus* was isolated from the throat on August 9 and from the blood on August 12. Intensive oral and parenteral sulfonamide therapy had no influence on the course of the infection, the clinical condition becoming progressively more critical with repeated embolizations and hyperpyrexia.

On admission to the Jewish Hospital she was virtually moribund. There was complete motor and sensory aphasia in addition to splinter hemorrhages under the nail beds of the toes and fingers and small ecchymotic areas on the volar surfaces of the fingers. Gallop rhythm was present, with heart sounds of poor quality. Blood culture on August 28 revealed 130 colonies of *Streptococcus haemolyticus* per plate. Penicillin therapy was started immediately, the dosage plan being 100,000 Florey units daily for thirteen days with the exception of the third day, when she received 200,000 units. Heparin, which was withheld pending the outcome of the recent cerebral embolization, was subsequently administered by the subcutaneous method, 300 mg. every other day on five occasions for a total of 1,500 mg. The sterile blood culture on August 31 and the reduction of temperature mirrored the dramatic clinical improvement. Toward the end of the second week of therapy the patient showed signs of pulmonary edema and, in view of the absence of bacterial activity, it was felt that the therapy could safely be interrupted. The patient was digitalized and fluid intake limited. During the succeeding four weeks her condition progressively improved, all embolic phenomena disappeared, the temperature ranged between 99 and 100 F., and blood cultures taken approximately at weekly intervals were sterile.

Occasional complaints of toothache prompted a dental survey at this time, which disclosed several badly diseased teeth. A two stage removal of these foci of infection was done under the customary precautionary penicillin regimen (see case 4).

The sedimentation rate dropped from 30 mm. per hour on September 2 to 14 mm. per hour on October 25 and routine periodic blood cultures were sterile. The clinical improvement continued satisfactorily, the temperature, which hovered between 99.4 and 100.2 F. for several weeks finally became normal, and the patient was discharged in good condition on November 17.

CASE 7.—Subacute bacterial endocarditis. *Streptococcus viridans*, ten weeks; chronic rheumatic cardiovascular disease, mitral; repeated, cyclic, massive sulfonamide therapy unavailing; satisfactory response to a two weeks course of penicillin-heparin therapy; progressive clinical improvement and complete absence of bacterial activity over two months; post-therapy, prophylactic tonsillectomy.

I. S., a man aged 35, was admitted to the Jewish Hospital of Brooklyn on Aug. 8, 1943 with complaints of chills and fever of ten weeks' duration. On the tenth day of his illness he had sudden, sharp, severe left upper quadrant pain, which receded after twenty-four hours. He entered another hospital, where a provisional diagnosis of typhoid was made. He was told that he had a large spleen but that all laboratory tests, including blood cultures, had been negative. He remained in the hospital for three weeks, the last ten days of which were afebrile.

Two weeks before admission to the Jewish Hospital the patient began to have chills and fever with daily spiking of temperature. His past history revealed an episode of "rheumatism for two months" at the age of 5. On entrance the temperature was 100.6 F., pulse 120, respirations 30 and blood pressure 120/80. The skin was pale with slight café au lait tint. There was a systolic blowing murmur at the apex, and the spleen was palpable 2 fingerbreadths below the costal margin. Blood culture done the day of admission revealed 40 colonies of *Streptococcus viridans* per cubic centimeter and confirmed the clinical diagnosis of subacute bacterial endocarditis. On August 11 combined sulfonamide-heparin therapy was started. The chemotherapy was of the massive, cyclic variety and consisted of 20 to 40 Gm. of sodium sulfadiazine,

30 to 60 Gm. of Zeitz filtered urea and 1 to 2 Gm. of ascorbic acid given on two successive days at approximately weekly intervals. Heparinization was accomplished with 300 mg. of the drug given subcutaneously approximately every other day. After the second cycle of therapy the blood culture taken during a post-transfusional febrile reaction yielded 7 to 12 colonies of *Streptococcus haemolyticus* per plate. The fifth and sixth cycles of chemotherapy (60 Gm. of sodium sulfadiazine) were started on September 10 and 17 without effect, as the blood cultures taken on September 14, 15 and 20 were all variously positive for *Streptococcus viridans*. It was evident at this point that the organisms were sulfonamide resistant and that massive chemotherapy had been futile despite levels up to 68.7 mg. per hundred cubic centimeters total and 59.0 mg. per hundred cubic centimeters free sulfadiazine.

On September 26 a fourteen day course of penicillin-heparin was started, the daily dosage consisting of about 200,000 Florey units of penicillin and 200 mg. of heparin dissolved in 1,500 cc. of isotonic solution of sodium chloride and given by continuous intravenous drip. The total penicillin administered was 3,203,200 Florey units, and the overall total of heparin was 6,700 mg. The temperature, which was irregularly lower during therapy, promptly dropped to normal following cessation of therapy on October 10 and has remained so to date.

Chart 9.—Course in case 7.

The sedimentation rate receded from 100 mm. per hour on August 9 to 24 mm. per hour on November 15, and repeated blood cultures have been sterile. The weight has increased from 143 pounds (65 Kg.) on September 12 to 153 pounds (69 Kg.) on November 21. The patient is in excellent condition and is awaiting discharge following the removal on November 22 of frankly infected tonsils, from which pus could be extruded. The prophylactic tonsillectomy was done under the customary, precautionary penicillin regimen (see case 4). *Streptococcus viridans* was the predominant organism in cultures of the removed tonsils.

SUMMARY

1. Seven consecutive patients with subacute bacterial endocarditis have been treated by a method which combines the uses of penicillin and heparin. Further observation will be required to determine the permanence of results, but the immediate effects suggest uniformly successful sterilization of the blood and relief of clinical manifestations.

2. Penicillin has been given in requisite dosage by the method of the continuous intravenous drip. One patient, however, also received the drug intramuscularly.

3. Heparin has been deposited subcutaneously in most instances but was occasionally given in the intravenous infusion.

4. There has been no significant toxicity as the direct result of therapy. In point of fact, treatment was well tolerated and each of the patients exhibited striking well-being during and after the active period of treatment.

5. In a few of the patients the efficacy of the therapy may have been enhanced by the preliminary use of sulfonamide.

6. Post-therapy management included the removal of possible foci in the teeth and nasopharynx. These surgical procedures were accompanied by additional prophylactic chemotherapy with penicillin.

COMBINED HEPARIN AND CHEMOTHERAPY IN SUBACUTE BACTERIAL ENDOCARDITIS

LOUIS N. KATZ, M.D.

CHICAGO
AND

CAPTAIN STEPHEN R. ELEK

MEDICAL CORPS, ARMY OF THE UNITED STATES

It has been shown previously by experimental work from this department¹ that the cause for the persistence of infection of *Streptococcus viridans* in a valvular vegetation is due to (a) the relative avascularity of the valve leaflets, (b) the presence of a fibrin-platelet barrier which interferes with the entrance of white blood cells and hinders the diffusion into the lesion of bacteriostatic and bactericidal agents present in the blood stream and (c) the fibrin constantly being added, which offers an excellent medium for the growth of these bacteria. On this basis it was thought that the prevention of further deposition of fibrin might be achieved with heparin, thereby permitting the vegetation to heal. The first case of subacute bacterial endocarditis treated with heparin was reported from this department.² Simultaneously Kelson and White³ reported their experience with 7 patients treated with heparin combined with sulfonamide therapy.

Since then combined heparin and sulfonamide therapy has been tried by many. Sixty-seven patients so managed have been tabulated and thoughtfully reviewed by McLean, Meyer and Griffith.⁴ Since then several additional cases have been reported.⁵ The latest tabulation⁶ lists 109 such cases. In this report we are placing on record 4 additional cases treated by us since publication of our original report. In 2 of these, intensive arsenotherapy was combined with the heparin and sulfonamide therapy because of the favorable report of Osgood.⁶

Aided by the A. D. Nast Fund for Cardiovascular Research. Drs. W. W. Hamburger (deceased), Sidney Strauss and Morris Lev gave valuable service as clinical consultants.

From the Cardiovascular Department, Michael Reese Hospital. The department is supported in part by a grant from the Michael Reese Research Foundation.

REPORT OF CASES

CASE 1.—F. M., a white woman aged 34, who was admitted to another hospital during the first week in January 1941 because of a three weeks history of fever, malaise, chills and joint pains which developed several weeks after the patient had two teeth extracted in the preceding November, then developed headache, dyspnea on slight exertion, orthopnea and ankle edema. She had had rheumatic polyarthritides at the age of 9, with evidence of heart involvement sufficiently severe to compel her to restrict her activities during her adolescence and in her twenties. She took digitalis on several occasions.

At the previous hospital the diagnosis of subacute bacterial endocarditis was based on the presence of rheumatic heart disease, petechiae, fever, leukocytosis and seven positive blood cultures showing *Streptococcus viridans*. While there she received sulfathiazole orally for about two months and heparin for one day (but this did not prolong her clotting time). The chemotherapy had to be discontinued because of persistent nausea. No clinical improvement was observed to result from the chemotherapy. On admission to Michael Reese Hospital on April 4, 1941 she appeared well nourished and well developed, with a café au lait complexion. The heart was enlarged, and murmurs characteristic of mitral stenosis and insufficiency and of aortic insufficiency were found. She had a Corrigan pulse, her blood pressure was 134/52 mm. of mercury and she had frequent premature systoles. The spleen was not palpable, and she had Janeway nodes on the soles of her feet. Eyeground examination showed blurred optic fundi and retinal petechiae.

The temperature was 102 F. by rectum, the pulse rate 116 per minute and the respiratory rate 22 per minute. The total white cell count was 15,600 with a shift to the left. The red blood cell count was 3,200,000 with 60 per cent hemoglobin. Two blood cultures were positive for *Streptococcus viridans*. There were 4 to 5 red blood cells per high power field in the urine sediment. The electrocardiogram revealed a sinus tachycardia, left ventricular preponderance and auricular premature systoles and was definitely abnormal. In the teleroentgenogram, the heart was bilaterally enlarged and the left auricle was dilated. During the patient's stay in the hospital petechiae, some white centered, appeared in the conjunctiva, on the hand and on the soft palate. Osler nodes of the fingers also were found.

The patient was started on sulfapyridine on April 14 but developed nausea on the same day and accordingly it was stopped. She was given heparin⁷ for seven days, from April 16 to 23. An average of 30 to 40 cc. per day was given intravenously dissolved in 2 liters of isotonic solution of sodium chloride. The total amount of heparin used was 262.5 cc. The clotting time was prolonged from 43½ minutes to from 12 to 25 minutes with a maximum of 36 minutes. The heparin was stopped on April 23 because the patient developed signs of cerebral hemorrhage. The patient died the next day. During heparinization her temperature fluctuated between 101 and 102 F. and she showed no clinical improvement.

The salient findings at necropsy were a subacute bacterial endocarditis on the aortic and mitral valves (superimposed on an old rheumatic valvulitis) extending to the left auricle, an acute myocarditis with small infarcts and a recent subarachnoid hemorrhage with hemorrhage into the left temporal lobe.

CASE 2.—B. S., a white woman, aged 27, admitted to Michael Reese Hospital on Dec. 4, 1940, complained of pain in the lower left leg. This first occurred in October and was followed three weeks later by a second similar episode lasting a week and accompanied by a chill. A local physician detected a double murmur over the apex and fever and informed the patient that she had acute rheumatic fever. She had had palpitation and orthopnea in the past one and one-half years and occasional ankle edema since 1936 and had lost 16 pounds (7.3 Kg.) preceding admission. There was no "rheumatic" history. In the past she had had measles, and, three years before admission, scarlet fever without any known sequelae. In 1938 she was diagnosed as having a toxic diffuse goiter and improved on strong solution of iodine (Lugol's solution).

7. Liquaemin, supplied for this and the other patients by E. R. Organon, Inc.

On admission the patient was pale, thin and ill looking with a temperature of 101.6 F. and she had a suspicious petechia on the right buccal mucosa. The heart was definitely enlarged, the apical impulse being close to the anterior axillary line in the sixth intercostal space. The heart sounds were of good quality. There was a fine systolic thrill at the apex, an apical systolic murmur and a questionable apical diastolic murmur. The heart rate was 100 per minute and the blood pressure 90/68 mm. of mercury. The spleen was palpable one finger's breadth below the costal margin and not tender. There were suspicious petechiae on the left leg, and early clubbing of the fingers was present.

The red blood cell count was 3,800,000 with 70 per cent hemoglobin, and the white blood cell count was 7,600. The urine was normal. Four blood cultures were positive for alpha hemolytic streptococcus; however, two subsequent blood cultures also revealed *Streptococcus viridans*. A teleroentgenogram showed the heart to be within average normal limits, and the left auricle was not dilated.

During the patient's course, petechiae in the eyegrounds and hard palate developed. Many Osler and Janeway nodes also appeared.

She was started on oral sulfanilamide on Dec. 24, 1940 and the blood level was maintained between 8 and 11 mg. per hundred cubic centimeters. This was stopped on Feb. 5, 1941 because of a toxic dermatitis. Sulfathiazole (15 grains [1 Gm.] alternating with 22½ grains [1.45 Gm.] every four hours orally) was then substituted and continued to April 4, but the maximum blood level attained was only 3.5 mg. per hundred cubic centimeters. During the five weeks on sulfanilamide therapy and the two months on sulfathiazole the blood cultures remained positive. On January 14 the patient was given heparin about cc. per day intravenously on the average. This was administered dissolved in 2 liters of isotonic dextrose-sodium chloride solution. Heparin was used without interruption continuously day and night for six weeks. The normal clotting time of six to seven minutes was kept prolonged at 20 to 25 minutes on the average with peaks up to 2 to 2½ hours. The total heparin used over the six weeks was 1,260 cc.

After two weeks of heparinization she was given massive arsenotherapy intravenously for four days. On the first day she received 120 mg. of mapharsen dissolved in 2 liters of isotonic solution of sodium chloride and on the other three days 240 mg. per day similarly diluted. A total of 840 mg. of mapharsen was given. On the fifth day the arsenotherapy was discontinued because of a toxic hepatitis from which the patient recovered. Heparin administration was continued during the arsenotherapy. The average temperature prior to arsenic therapy was about 100.6 F., but during it the temperature remained below 99 F. and at no other time in the patient's course did it approach normal levels.

This patient tolerated the protracted course of heparin very well but there was no evidence that it or the chemotherapy led to improvement clinically or had any crucial influence on her illness. Her course after therapy was stopped was progressively downhill. Crops of petechiae appeared in April; paroxysmal auricular fibrillation occurred in May associated with right hemiparesis which improved. She died on June 19 after seven months of hospitalization. Unfortunately permission could not be secured for a necropsy.

CASE 3.—E. G., a white woman aged 25, admitted to Michael Reese Hospital on Aug. 7, 1941, complained chiefly of paralysis of the right side of the body (without unconsciousness), which developed suddenly during a meal a day before admission. Two weeks prior to this she had had transient episodes of loss of speech and a retraction of the left corner of her mouth; during these episodes she had felt drowsy. She also complained of feeling weak and feverish and of pains and "red spots" at the tips of her fingers over the preceding eight weeks. She had lost 25 pounds (11 Kg.) in this same period. At the age of 9 she had chorea and since then had known about her rheumatic heart affliction. In 1940 she successfully bore a child and had an appendectomy.

On admission the patient was thin, anemic and acutely ill in appearance, her temperature was 100.4 F. and her pulse rate 110 beats per minute. The heart was slightly enlarged and the

murmurs of mitral insufficiency and stenosis were present, as well as a presystolic apical thrill. Her blood pressure was 120/80 mm. of mercury. The spleen was palpable one finger's breadth below the costal margin but was not tender. There were neurologic signs of previous cerebral embolism, but no paralysis or paresis was found.

The red blood cell count was 4,000,000, with 80 per cent hemoglobin. The white blood cell count was 11,000, with a shift to the left. The urine was normal. The stool contained occult blood. The electrocardiogram was normal. The teleroentgenogram revealed the configuration expected with mitral stenosis and insufficiency. Five blood cultures were positive for *Streptococcus viridans*.

The patient received sulfapyridine by mouth from August 14 to 22, the average blood level attained being 9.1 mg. per hundred cubic centimeters. This had to be discontinued because of severe nausea and vomiting. Sulfathiazole was later substituted for twenty-one days (September 5 to 26) and the average blood level was maintained at 2.5 to 4.0 mg. per hundred cubic centimeters.

Heparin was started September 9 and stopped September 17. The quantity used per day varied from 20 to 60 cc. intravenously, the average being 30 cc. This was administered dissolved in 2 liters of isotonic solution of sodium chloride. The blood clotting time was prolonged from a normal of 7 minutes to from 12 to 36 minutes, the average being about 25 minutes. Heparin was discontinued because of the suspicion of cerebral hemorrhage manifested by numbness and difficulty of movement of the left arm and leg. However, three days after stoppage of heparin administration sensation and motion of the affected extremities had returned. The blood cultures remained positive during heparinization.

In November the patient received oral sulfadiazine for twenty-six days (the blood level ranged from 5.9 to 13.9 mg. per hundred cubic centimeters) and an arsenical preparation, Solar-sen, 1 cc. per day intravenously for seven days. On November 26 she was given a total of 96 mg. of mapharsen by vein dissolved in 2 liters of isotonic solution of sodium chloride, but this was discontinued because of toxic symptoms. During all this therapy there was no evidence of clinical improvement. On December 1 the patient left the hospital against advice and returned nineteen days later in a state of disorientation with another recent hemiplegia. She died on December 30, five months after her first admission.

Necropsy revealed an old rheumatic endocarditis of the mitral valve with a superimposed ulcerating and vegetative subacute bacterial endocarditis with extension to the auricular endocardium. There were embolic manifestations in the skin, spleen, kidney, brain, coronary vessels and gastrointestinal tract. Microscopically the mitral valve showed granulation tissue, fibrin and bacteria engrafted on a fibrotic valve. The immediate cause of death was an extensive bronchopneumonia.

CASE 4.—G. G., a white girl aged 16 years, was admitted to Michael Reese Hospital on May 31, 1941 because of a feeling of weakness, night sweats and a fever of twenty-four days' duration. She also had had mild palpitation and dyspnea after excitement on moderate exercise for the previous six months. She had had rheumatic fever and rheumatic heart involvement at the age of 7 with three exacerbations.

On physical examination the patient appeared pale, thin and cyanotic. There was a systolic thrill in the carotid arteries. The cardiac apex was in the fifth intercostal space at the anterior axillary line. There was a systolic thrill over the aortic area. The murmurs of mitral and aortic insufficiency and of mitral stenosis were present. The pulse was of the Corrigan type, the blood pressure 110/0 mm. of mercury, and a pistol shot murmur was audible over the femoral arteries. The splenic edge could be palpated at the costal margin but was not tender. Early clubbing of the fingers was present.

The temperature was 100.4 F. The heart rate was 86 beats per minute. The red blood cell count was 3,640,000, with 65 per cent hemoglobin. The white blood cell count was 12,500. The urine was negative. The sedimentation rate was 33 mm. per hour. The electrocardiogram was definitely abnormal. The teleroentgenogram revealed an enlarged heart with the configuration expected with mitral and aortic valve involvement;

the left auricle was dilated. Three blood cultures were positive for *Streptococcus viridans*.

Sulfathiazole was given from June 14 to July 1 in doses of 15 grains (1 Gm.) every four hours. Sulfapyridine was begun on July 12 and continued until the 17th, 15 grains being given by rectum every four hours dissolved in 50 cc. of water. The blood level on the 16th was 1.7 mg. per hundred cubic centimeters. Between July 22 and 25 the drug was administered in doses of 2 to 5 Gm. intravenously. Nausea and vomiting accompanied each period of sulfonamide administration.

Heparin was given between July 22 and 26; 15 to 25 cc. was given intravenously per day, the total being 105 cc. The heparin was administered dissolved in 2 liters of isotonic solution of sodium chloride. Heparin prolonged the clotting time from 4 minutes to from 11 to 57 minutes, the average being 26 minutes. All therapy ceased on the 26th, when the patient left the hospital against advice and track was lost of her. The therapy appeared to have had no beneficial effect clinically, the fever persisting and the blood cultures remaining positive.

COMMENT

All 4 patients were young women suffering from *Streptococcus viridans* endocarditis of varying duration before therapy was started. No benefit appeared to have been derived from the therapy given in any of these cases aside from the drop in temperature to normal levels in case 2 during the four days of massive arsenotherapy with mapharsen. Our experience that massive arsenotherapy may temporarily relieve the fever is similar to that reported by Druckman⁸ in a patient who received a total of 3.6 Gm. of neoarsphenamine over four days. However, this was heroic therapy and had to be stopped in both of our cases because a toxic hepatitis developed. Furthermore, the drop in temperature was not seen in the other case (case 4) in which we employed arsenotherapy. The sulfonamides not only were not beneficial in our cases but also had to be stopped because of toxic symptoms on several occasions in all our cases except when the blood levels were too low. The addition of heparin given for five, seven and nine days in 3 of our cases and for six weeks in case 2 did not lead to clinical improvement in any of these cases. In fact, in case 1 it resulted in a fatal cerebral hemorrhage, and it may have been responsible for a nonfatal milder episode of a similar character in case 3.

Case 2 represents the longest period of continuous heparinization recorded in the literature and, while no benefits were obtained clinically, no harm resulted. The possibility that this prolonged heparin treatment may have favored at least partial healing of the vegetations and contributed to prolonging the patient's life could not be determined, since necropsy examination was not permitted.

Our original idea,¹ and the same suggestion was also made by McLean and his associates,⁴ was that the efficacy of heparin could be best studied by administering it alone, as the blood in this disease is known to have a high antibody titer, the problem being one of sterilizing the bacterial vegetations rather than sterilizing the blood stream. In our case¹ and in the 2 cases reported by Leach and his co-workers⁹ heparin alone was ineffective. Other similar reports have appeared.¹⁰

Combined therapy was tried in the present study as it doubtless was by others in order to seek out

a combination, simple or complex, which would act on the vegetative lesion and lead to statistically significant clinical recoveries. Recently assays of the literature on the therapy of subacute bacterial endocarditis have been assembled¹¹ which at first sight tend to suggest that sulfonamide therapy, especially when combined with heparin or hyperthermia, has led to a somewhat greater percentage recovery than occurs spontaneously or with nonspecific therapy. Thus, in a summary of the literature it was reported by Smith, Sauls and Stone¹¹ that of 634 untreated or nonspecifically treated patients 1 per cent recovered, while the rate of recovery was 6 per cent in 198 patients treated with sulfonamides, 11.5 per cent in 43 patients treated with sulfonamides and heparin and 18 per cent in 46 patients treated with sulfonamides and physical hyperthermia or intravenous typhoid. Later, Lichtman⁵ assembled a larger series from the literature and noted 1 per cent recoveries in 2,956 untreated or nonspecifically treated cases, as against 4 per cent recoveries in 489 cases treated with sulfonamides, 6.5 per cent in 109 cases treated with sulfonamides and heparin and 10 per cent in 106 cases treated with sulfonamides plus physical hyperthermia or intravenous typhoid. These apparently favorable records, however, are no more than suggestive, since the series are small and may not be statistically significant. It may be significant that the percentage of recoveries in the later report is lower than in the earlier one on a smaller series. Furthermore, it is obvious that negative results are less apt to be reported than positive ones. It is also easy to confuse a long spontaneous remission which occurs in this disease with recovery attributable to the therapy used. The possibility also exists that, in some of the cases reported in the literature as subacute bacterial endocarditis, *Streptococcus viridans* was simply the organism causing a septicemia without having led to subacute bacterial endocarditis. Such a circumstance has been reported.¹² A final judgment as to which, if any, of these plans of therapy is efficacious must therefore await future analysis, and it is proper when utilizing such therapy to consider it still in the experimental stage.

If the use of sulfonamide therapy, either alone or combined with heparin, is based on the hope that the agent may penetrate into the vegetation and there check the continued growth of the organism, thereby permitting the vegetation to heal, this healing effect should be demonstrable on postmortem examination. While accelerated healing has been reported in a few treated cases post mortem,¹³ in most of them,¹¹ including the 2 of our present series in which necropsies were done, there is little effect in the valves which could be ascribed to specific therapy rather than to the usual tendency to healing typical of this disease. As Leach and his co-workers⁹ state, "Postmortem examination in several cases revealed little effect on the vegetation from either the chemotherapy or the heparin. . . . It was the rule to find the vegetations swarming with organisms in spite of high antemortem blood levels of sulfonamide." Kelson⁹ alone states that an unusual degree of healing occurs.

One risk in heparin therapy is the high incidence of bleeding. Of the 67 cases tabulated from the literature by McLean and his associates¹ which came to necropsy 11 showed evidence of hemorrhage, usually cerebral, in 9 of which death occurred. Renal hemorrhage has also been reported. Two of our 4 cases, as well as the first case previously reported by us,¹ also showed clinical and/or necropsy evidence of cerebral hemorrhage. Of 22 patients treated with heparin and sulfonamides, 8 died of cerebral hemorrhage during the time heparin was given. Several other authors¹⁵ have commented on this harmful sequel to administering heparin in this disease. Only Kelson¹⁶ appears to have been fortunate in avoiding the hazards of heparin, since he states that cerebral bleeding occurred in none of his cases. There are in addition a number of difficulties in the control and management of patients during heparinization. Thus our patient receiving heparin for six weeks required constant care and attention in order to be sure of needle placement and to keep the clotting time within set limits.

It is the consensus, to which we add our own experience, that the disadvantages of heparin, used alone or in conjunction with chemotherapy, in the treatment of subacute bacterial endocarditis heavily outweigh its advantages. Friedman,¹⁶ who participated in the development of the idea of the use of heparin in this department, subsequently concluded that the further use of heparin should be abandoned in subacute bacterial endocarditis. This view has been voiced by others,¹⁷ after surveying the reports in the literature and our own further experience, we take this opportunity to go on record as concurring in this opinion.

The therapeutic value of arsenotherapy in subacute bacterial endocarditis has recently been advanced by Osgood,⁶ who reported 14 per cent apparent recoveries in 70 cases. Lippmann¹⁸ has reported a case with apparent recovery following the use of sulfonamide combined with arsenotherapy (Solarsen). It was these reports that stimulated us to try out the effects of arsenotherapy in combination with heparin and sulfonamides. Our experience in 2 cases were negative, so that we feel that arsenical therapy also is still in the experimental stage. If used in intensive doses its administration must be carefully watched because of the hazard of toxic reactions.

SUMMARY

In 4 cases of combined heparin and chemotherapy, either sulfonamides or sulfonamides and intensive arsenotherapy in the treatment of subacute bacterial endocarditis due to *Streptococcus viridans*, the results were entirely negative, no evidence of clinical recovery being seen. In 2 of the 4 cases evidence of cerebral hemorrhage during heparin administration was found, making a total of 3 out of 5 cases studied by us.

In 1 of our cases it was possible to administer fairly large quantities of heparin continuously intravenously for six weeks without ill effects. This is the longest period of such administration on record.

In view of this experience and that of others reported in the literature, it is concluded that the further use of heparin in subacute bacterial endocarditis should be abandoned.

CHEMOTHERAPY IN OPHTHALMOLOGY

PARKER HEATH, M.D.

DETROIT

Medical science in the past few years has developed chemical compounds high in bacteriostatic effect and low in local irritant or general harmful reaction. The sulfonamides are widely used in this capacity, and other compounds made from bacillary or mold extracts offer high therapeutic promise. The rapidly expanding use of chemotherapy travels with more knowledge of how these agents work and why they fail. Selection of the substance used becomes more important as physicians learn under clinical conditions the rates of absorption and elimination, the solubility and effective concentrations, the toxicity and side reactions—in short, the specificity of each compound. When several agents are equally effective in meeting a clinical problem, low toxicity and freedom from sensitization reactions or late harmful effects should govern selection. Rapid and known specific effects may outweigh in value the factor of low toxicity. From the comparative safety of low dosage some are led to employ the sulfonamides non-specifically. This is not good practice in general because there are usually enough directives for specificity. Also there are possibilities of establishing early sensitivity, and late unknown reactions may follow tampering with immunity processes.

Toxic side effects are not uncommon with the widely used sulfonamides. They relate chiefly to the hemopoietic system and the urinary tract. The ocular field may show edema and dermatitis of the eyelid, conjunctivitis, clouding of the media and orbital edema, and the second nerve may show reaction. The skin of the eyelids and face may present an appearance of a dermatitis from external sources, or vesiculation, or deep edema and cellulitis or both—sometimes not unlike erysipelas. In some instances effective concentrations of a sulfonamide may be maintained and sensitivity corrected by switching to another compound. In other instances the sensitivity seems to be related to the sulfonamide ring; it then becomes necessary to employ less related substances, as the extracts of molds or bacteria. Established effective methods of therapy need not be discarded in favor of something new. With the right to prescribe the medicament should go the responsibility of continued study of the patient. The ambulatory patient should use sulfonamides only with enforceable restrictions and checks. The daily excretion of urine should be 1,500 cc. or more. With extra fluid intake and added sodium bicarbonate, urinary complications are reduced. When the rare complication anuria develops, catheterization and flushing out of the ureter should follow stoppage of the drug. Differential blood counts are necessary. "Blood levels at least every two days" is a good rule.

The effective dosages and concentrations are variable with the same drug in different infections and patients. To be more fully worked out are combinations of the sulfonamides with other substances—with urea to increase solubility and concentration, with pus and paraaminobenzoic acid in excess to reduce inhibitors, with zinc compounds to augment the effect and permit lowered concentrations, with vasoconstrictor to produce less capillary congestion and local absorption. Drug fastness is an important problem for solution. Much

remains to be learned about enlarging the scope of these substances by methods common and unusual in pharmacologic research.

SPECIFIC SUGGESTIONS

Inclusion Blepharitis.—Sulfathiazole is used. The oral dosage is one-third grain (0.022 Gm.) per pound daily in divided doses. This dosage is discontinued after the fourth to seventh day. Local treatment consists of antiseptic washes and the use of 5 per cent sulfathiazole ointment at night.

Gonorrheal Ophthalmia or Gonorrheal Conjunctivitis.—These conditions are effectively treated by oral doses of sulfapyridine, sulfathiazole or sulfanilamide. For an adult the initial oral dose is 3 to 4 Gm.; subsequently 1 Gm. is given every four hours. For a child the dosage is one-third grain (0.022 Gm.) per pound of body weight in divided doses daily; the initial and second doses may be larger to hasten the effect. Local treatment is in order with an ice compress for much edema (occasionally canthotomy), antiseptic irrigations, an ointment containing a sulfonamide compound, atropine if indicated and a conjunctival flap for ulceration and imminent perforation. The powdered drug is used locally with success by some. The use of sulfonamides should be continued until smears are negative for two days.

Hemolytic Staphylococcus Conjunctivitis.—The general treatment consists in the administration of staphylococcus toxoid, the local treatment in the application of a zinc ointment containing sulfathiazole 3.0 per cent and an ointment containing sulfadiazine or sulfathiazole 5.0 per cent twice daily. The conjunctiva should be washed with an antiseptic solution four to six times a day.

Pneumococcal Conjunctivitis.—Tyrothricin (except Friedländer's type) 30 mg. per hundred cubic centimeters is dropped freely into the eyes four to six times daily. For pneumokeratitis and ulcer the same dosage of tyrothricin is used with oral administration of sulfapyridine or sulfadiazine, 2 to 4 Gm., initial dose, followed by 1 Gm. every four hours around the clock. Locally one may use atropine, the cautery and, if indicated, paracentesis and delimiting keratectomy. Foreign protein and typhoid-paratyphoid vaccine have proved value.

Traumatic Injury.—The eye and its parts have a rich blood supply, usually favorable to repair. Foreign matter is removed, and minimal débridement is done. Free local application of a sulfonamide compound or of a preparation of Penicillium when available lessens the possibility of infection and permits more complete early repair. General chemotherapy is necessary for severe ocular lacerations and penetrating wounds of the globe, especially if infection is suspected.

Epidemic Keratoconjunctivitis—Shipyard Fever.—The most favorable results to date have followed local use of tyrothricin 30 mg. per hundred cubic centimeters four to six times daily. Few favorable results have followed the use of zinc ointment containing sulfathiazole 3.0 per cent and other sulfonamide compounds in combination with other drugs. Convalescent serum has not been consistently useful.

Specific Keratitis and Ulcer Due to Bacillus Pyocyaneus.—This requires early treatment (a matter of hours) with sulfapyridine or sulfadiazine; the initial dose is 4 to 5 Gm.; it is followed in one hour by 2 Gm., and thereafter by 1 Gm. every four hours around the

clock. The treatment is continued for ten to twenty-one days, the dosage being regulated by blood levels and the clinical course.

Dendritic Keratitis.—Local and oral use of the sulfonamides has not been of much value. Local application of tyrothricin 30 mg. per hundred cubic centimeters with repeated pasteurization by cautery (daily or on alternating days) has led to the most rapid cure.

Blepharitis.—Blepharitis and that form of punctate keratitis associated with chronic conjunctivitis (usually caused by a staphylococcus) are sometimes cured by using sulfadiazine or sulfathiazole ointment three to six times a day. Tyrothricin is helpful (20 mg. per hundred cubic centimeters). The compound neosynephrine sulfathiazolate 3.0 per cent has relieved some obstinate cases.

Orbital Abscess.—Sulfadiazine, sulfapyridine or sulfathiazole is used. The initial oral dose for adults is 2 to 5 Gm., which is followed by 1 Gm. every four hours around the clock. For children the doses are reduced proportionately. Other measures, such as the use of hot wet dressings and drainage, must be considered.

Thrombosis of the Cavernous Sinus.—Hope of cure is offered by a high dosage of sulfadiazine. A rather high blood level should be maintained for three to six weeks. Treatment must be prolonged to prevent relapses.

Uveitis.—The eye with acute uveitis is helped in some cases by the oral use of sulfonamide drugs. Indiscriminate use of these drugs is to be avoided. Sulfadiazine and sulfapyridine have proved about equally effective. When the source of the uveitis is related to the gastrointestinal tract, sulfadiazine and sulfapyridine offer help. The key to successful treatment is to attack the causative agents. In a moderate degree of iritis recovery is sometimes hastened by the use of sulfonamide compounds. Choroiditis is least affected by such treatment. Sympathetic uveitis or ophthalmia so far has been unevenly affected either by high dosage for short periods or low dosage over long intervals. This ocular catastrophe justifies continued clinical investigation to determine the value of its treatment by chemotherapeutic agents.

Trachoma.—The oral dosage of sulfanilamide is 2 Gm. and then 1 Gm. every four to eight hours over a period of a week or ten days. It seems definite that secondary infections are reduced and that the majority of physicians using this drug have noted definite improvement from the disease, especially from corneal involvement.

Postoperative Infections.—Infection following intra-ocular surgical work usually manifests itself on the second or third day. Continued pain after the initial surgical reaction should have subsided is suspicious, and the eye should be inspected. One should not wait for the usual forty-eight or thirty-six hour interval. An infective process may be stopped by the use of sulfadiazine or sulfapyridine. The oral dosage is 4 to 6 Gm., initial dose, followed by 2 Gm. at the second and the third hour and thereafter by 1 Gm. every four hours around the clock. Continued treatment is usually indicated up to ten to twenty-one days, depending on the severity and the results obtained.

Late Infection After Trephining, Enophthalmos.—This process may be stopped by the use of sulfapyridine or sulfadiazine. The initial oral dose is 4 to 6 Gm.;

at the second and the fourth hour 2 Gm. is given and thereafter 1 Gm. every four hours around the clock. A cyclitic cataract may develop in this profound inflammation, and secondary glaucoma may develop associated with the lens swelling, requiring removal of the eye if other treatments fail.

Low Grade Dacryocystitis.—Strictures may be prevented and inflammatory processes resolved in some cases by irrigating through the lacrimal sac with tyrothricin 30 mg. per hundred cubic centimeters, every three to seven days. Some eyes are helped by the use of finely divided sodium sulfathiazole used as an emulsion. Treatment must continue over a period of months.

1553 Woodward Avenue.

ABSTRACT OF DISCUSSION

DR. ALAN C. WOODS, Baltimore: I agree with Dr. Heath as to the preparations to be taken in the administration of these drugs. Patients treated with these agents should be admitted to the hospital, and only in exceptional instances, and then with the restrictions outlined by Dr. Heath, should these drugs be administered to ambulatory patients. As concerns the "specific suggestions" offered by Dr. Heath in gonorrheal ophthalmia, traumatic cases, orbital abscesses, trachoma, postoperative infection and late infections after trephine operations, our experiences with these drugs in the Wilmer Institute has been similar to his. In other instances, notably with tyrothricin, our experiences have not been so happy. While tyrothricin *in vitro* is efficacious against the gram positive organisms and theoretically should be of considerable value in the treatment of infections with such organisms, in our hands its practical value is very doubtful. The action of the substance differs from that of the sulfonamides in that it is bactericidal instead of bacteriolytic. It is also toxic to tissues, causing damage to the corneal epithelium if used frequently and lysis of the red blood cells if given parenterally. It is a large molecule, does not penetrate tissues deeply after local application and is therefore little more than a tissue cleanser. In chronic dacryocystitis we have found it of no value. We have not used it in epidemic keratoconjunctivitis or dendritic keratitis. In experimental dendritic keratitis it did not alter or shorten the course of infection in rabbits. In the treatment of endogenous uveitis with sulfonamides our experiences have been constantly disappointing. In recurrent iritis, tuberculous uveitis, choroiditis and sympathetic ophthalmia the use of sulfonamides has repeatedly been without any clinical effect. In such specific conditions as metastatic meningococcic endophthalmitis the results from sulfonamide therapy have been spectacular. In general, excepting such specific instances, I am of the opinion that the use of sulfonamide therapy in endogenous uveitis is not justified. The present indications are that penicillin will probably be our most effective agent in combating infections with the gram positive organisms.

DR. WALTER S. ATKINSON, Watertown, N. Y.: The non-specific use of the sulfonamides should be avoided. The selection of the drug should be based on a precise knowledge of the bacteria concerned and the sulfonamide compound chosen that has the greatest bacteriostatic effect on the particular bacteria present. The empirical use of the sulfonamides locally, as for postoperative medication, is not only of questionable value but is contraindicated because it delays healing. Since the penetrability of the sulfonamide compounds varies greatly, particularly in regard to the eye, it is important to select the compound that penetrates the ocular tissues most readily so that a sufficient concentration can be maintained in the affected part. Methods suggested by Dr. Heath to increase the penetrability, and so the concentration of the sulfonamide compounds in the ocular tissues and fluids, should be carefully considered. The use of such measures as heat, iontophoresis or oxidizing agents which reduce the surface tension has been shown to increase the penetrability of the sulfonamides. The consensus is that in most instances a large dose of the sulfonamides for a short

period is preferable to a small dose over a long period. Inadequate concentrations of the drug not only may be ineffective in combating the infection but may produce hypersensitization or a sulfonamide fast organism. In ambulatory patients the sulfonamides should be used only with enforceable restriction and checks. In hospital patients the occasional complication of anuria might be avoided if the fluid intake and urinary output is watched closely. Frequent estimation of the blood level should be stressed. If an adequate concentration is not maintained, the purpose of the treatment is not accomplished and harmful reactions may be produced so that larger doses given later may be of little avail. Dr. Heath's concise paper with his specific suggestions is an excellent guide for ophthalmologists and should stimulate a desire to acquire an exact knowledge of the action and use of the new chemical compounds.

DR. JOHN G. BELLOW, Chicago: I should like to enlarge on a few points in the administration of sulfonamides. Oral administration is indicated when infection begins in the interior of the eyeball or orbit or has progressed beyond the reach of topical application, and in trachoma or gonorrheal conjunctivitis. In some conditions both oral and local administration may be the best form of therapy. A simple way to increase the concentration of sulfonamides in the cornea and the aqueous is by the addition of wetting agents such as aerosol or tergitol. Gutmann and I have shown by this means that the concentration in the cornea and aqueous can be increased fifteen-fold or more. Thus in some infections of the anterior segment of the eyeball this method, by decreasing the need for oral administration, diminishes the incidence of toxic reactions mentioned by Dr. Heath. Topical application of sulfonamide compounds to the eye is governed by certain local conditions. Sulfonamides are bacteriostatic; therefore, in the avascular cornea, the drug will be less effective than in a vascularized tissue which contains a full complement of leukocytes. Detritus, secretion and certain local anesthetics decrease the local effectiveness of sulfonamides. The drugs must be used with caution in traumatic lesions of the cornea, because in the absence of normal epithelium they cause a severe injury as shown not only by delaying the healing of the corneal epithelium but also by promoting the formation of scar tissue. Therefore in corneal abrasions and injuries the local use of a sulfonamide compound should be limited to cases in which dangers of infection outweigh the cosmetic and visual factors. I wish to add to Dr. Heath's discussion of the treatment of epidemic keratoconjunctivitis that sulfathiazole desoxyephedrine decreases rapidly the pain, lacrimation, redness and swelling associated with this disease without influencing the degree of scarring.

DR. RICHARD C. GAMBLE, Chicago: The specific suggestions Dr. Heath makes for treating the commoner ocular diseases set a standard which can be safely followed. I am in agreement with his suggestions with regard to inclusion blennorrhea, gonorrheal ophthalmia, hemolytic staphylococcus conjunctivitis and pneumococcic conjunctivitis. In regard to traumatic injuries, especially those with corneal abrasion, I would suggest less local use of sulfonamides and greatly stress the general use of them. There is no doubt that the local use delays healing and may cause more scar. There is also no doubt that the internal administration of sulfonamides is of great value in infected, perforating or lacerating injuries, both prophylactically and after infection is present. In regard to epidemic keratoconjunctivitis, I have had no experience with tyrothricin. I have never seen any benefit from sulfathiazole ointment in this condition and have felt in several instances that it was harmful. It is difficult to evaluate the effect of internal sulfonamide therapy in cases of orbital abscess. In all probability many abscesses are prevented by this type of treatment for severe colds and sinus infections. If the abscess develops, however, it usually has to be drained. The sulfonamides do not cause it to absorb, but the pain and general prostration are perhaps lessened. It is unfortunate that Dr. Heath did not give more space to the subject of uveitis. In my experience this treatment has been very good in cases of iritis with hypopyon, even when gonorrhea could not be proved as the cause. It has been entirely useless in the more chronic types except (and I do not know why) in sympathetic ophthalmia, where it

seems to hold the disease process in check, giving time for the natural healing processes of the ocular tissue to act. The important thing is to hold the cellular exudate and subsequent fibrosis to a minimum until the disease becomes inactive, because the exudate and fibrosis are the factors which obstruct the pupil and cause the secondary glaucoma and the opacities of the lens and cornea.

DR. PARKER HEATH, Detroit: The discussers have recognized that different therapeutic results are inevitable since variations in virulence of the infecting agent and individual immunity meet different methods of therapy. Mention of any one therapeutic substance gives a false emphasis to its values. Tyrothrycin is an example. Dr. Woods has pointed out its limitations used alone. Dr. Atkinson has given necessary emphasis to need for precaution in use of sulfonamide and similar compounds. Dr. Bellows has reported some methods of increasing penetration locally by means of vehicles which alter surface tension. Both he and Dr. Gamble warn of local use producing delayed healing and increased corneal scarring in abrasive lesions. The discussers are largely in agreement on the use of the conventional chemotherapeutic agents. A possible exception would be in the therapy of uveitis. Since these discussions simply report without elaboration, further details will have to be presented at another time. It is likely that there will be many new synthesized substances, especially in the acridine group, of high potency, diversity and relative safety in use. It is also likely that the leukopenia occasionally noticed with sulfonamide compounds may be prevented, but the responsibility increasingly remains with the physician to know the cause of the disease and then to prescribe the treatment.

DEMEROL

CAUTION IN ADMINISTRATION TO PATIENTS WITH INTRACRANIAL LESIONS

SAMUEL A. GUTTMAN, M.D., PH.D.
NEW YORK

In 1939 Eisleb and Schaumann¹ introduced 1-methyl-4-phenyl-piperidine-4-carboxylic acid ethyl ester hydrochloride as a compound which possessed so-called spasmolytic properties along with an analgesic action. During the past five years several score papers have appeared on the action of demerol, and it has been studied in both animal and human experiments. There are several reports which indicate that demerol may be associated with habit formation² and there is one case report in which demerol is reputed to have induced a delirium.³ Batterman⁴ states that the drug should be administered with caution to ambulatory and elderly patients because of the high incidence of dizziness and the possibility of syncope. I am not aware of any other reports on the human being which indicate any untoward or undesirable response to this drug other than phenomena classified as side effects, the more usual of these are dizziness, perspiration, dryness of the mouth and nausea.

The Winthrop Chemical Company of New York supplied the demerol. Demerol is known as eudalol, dolantin, dolantol and pethidine in other countries.

From the Neurological Institute of New York and the Department of Neurology, Columbia University College of Physicians and Surgeons.

Batterman and his colleagues⁵ found that demerol (usual dose 100 mg., range 50 to 150 mg.) was "a potent, effective, and safe (medication) for the relief of pain due to a variety of medical and surgical conditions" and that "respiratory depression occurred rarely," in only 2 of the 774 patients who received demerol parenterally. Therefore it was deemed worth while to investigate the effect of demerol on patients

TABLE 1.—Distribution of Lesions

Lesions	Number
Right frontal meningioma	1
Cerebellar hemangioma	1

with intracranial lesions, in whom morphine sulfate is usually considered contraindicated because of its depressant effect on respirations and the alteration in pupillary response.

The observations listed in table 1 were made on 20 patients who had intracranial lesions. These patients received 100 mg. of demerol parenterally (unless stated otherwise) into the deltoid region. Data including blood pressure, pulse and respiratory rate were obtained before the drug was administered, and the so-called vital signs along with other pertinent observations were made at least each fifteen minutes, almost always by the same observer, for about three hours after the administration of demerol. All patients remained in bed during the course of these observations. Since the primary purpose of the study was an attempt to evaluate the safety of demerol in the type of case under consideration, I am including only those observations which are directly related to the question at hand. Hence, only those patients who showed what was considered an unsafe respiratory depression (a rate of 12 or less per minute for at least fifteen minutes) will be discussed in some detail. Seven individuals fell into this category; in five the rate fell to 12 per minute, while in 1 the rate went to 8 per minute and in another it reached a low of 4 respirations per minute. In the remaining 13 patients the respiratory rate fell from the premedication value of 18-22 per minute to a low of 16-18 per minute in 9 patients, 15 per minute in 3 and 14 per minute in 1.

TABLE 2.—Observations in Case 1

was a depressed fracture of the anterior wall of the left frontal sinus. There was persistent headache and dizziness but no drowsiness, nausea or vomiting. The left pupil was dilated, and there was a preponderance of the deep reflexes on the right side. The spinal fluid was xanthochromic for several weeks after admission, and at first the protein was elevated. This patient suffered from a cerebral concussion aside from his other injuries.

TABLE 3.—Second Series of Observations

Time in Minutes	Comment	Pulse	Respiration	Blood Pressure
0	Demerol 100 mg.....	64	18	110/70
15	60	18	
25	Diaphoresis; drowsiness.....	58	17	
40	Headache eased; mouth dry.....	57	14	108/70
55	Very drowsy; slight headache.....	59	9	100/70
60-90	Pupils contracted—sluggish.....	56-60	12	105/70
105	Drowsiness.....	60	14	100/70
120	Pupils no longer contracted.....	60	18	
135-210	Became alert; headache returned..	60-64	14-20	90/65 100/70

On the sixth hospital day he was given 50 mg. of demerol by mouth. Within half an hour he became drowsy, his pulse rate fell from 72 to 52 per minute and his respiratory rate ranged between 18 and 20 per minute. Within two hours he was alert. His headache, which had eased but did not disappear, began to increase. There was never any significant change in blood pressure.

Four hours after this initial dose the patient received 100 mg. of demerol in the deltoid region.

On the seventh hospital day the patient received another 100 mg. of demerol parenterally. The pulse fell from 64 to a minimum of 56 and the respirations from 18 to 14 without a significant change in blood pressure. The patient reported only 0 per cent relief of headache." He experienced nausea and vomiting and had contracted pupils. All these symptoms and signs persisted for about an hour.

On the ninth hospital day 100 mg. of demerol was again administered parenterally (table 3).

On the fourteenth hospital day the patient received 50 mg. of demerol by mouth without any especial change in pulse, respirations or blood pressure. No side effects were noted, and the patient's severe headache was not altered. Four hours later another 50 mg. was administered, and no untoward response was noted except for the fact that the respirations fell to 14 per minute. The patient did not notice any amelioration of his headache.

CASE 2.—M. P., a man aged 36, was admitted five days after a generalized seizure. Since the convulsion he had had severe bifrontal headaches, nausea and vomiting. The patient was restless and had bilateral papilledema of 1.0 to 1.5 diopters with fresh flame shaped hemorrhages. Subsequent craniotomy revealed a right frontal astrocytoma.

Two days after admission the patient received his first dose of demerol (table 4).

TABLE 4.—Observations in Case 2

Time in Minutes	Comment	Pulse	Respiration	Blood Pressure
0	Demerol 100 mg.....	50	19	105/70
15	Severe headache persists.....	52	19	120/90
30	Nausea, vomiting, diaphoresis....	48	12	110/80
45	Headache has eased considerably..	47	12	110/80
60-120	Free from headache; drowsiness..	46-54	14-16	100/70
210	Headache returning.....	61	18	

On the fourth hospital day another 100 mg. of demerol was administered. There was rather a similar sequence of events. Within forty-five minutes the respirations dropped to 12 per minute for half an hour, and during this period the respirations were irregular. The pulse slowed, and there was no significant change in blood pressure. The patient had a pronounced diaphoresis, nausea and vomiting. Incidentally he did not have any nausea or vomiting during the preceding twenty-four hour period. The patient was drowsy for about two hours and there was some relief from the severe headache, but this was not very definite.

CASE 3.—C. McC., a woman aged 50, was admitted with a history of "depression" for five months and confusion and lethargy for two weeks. The patient also suffered from headaches and at the time of admission she was somewhat confused and exhibited a right hemiparesis with decidedly overactive reflexes, more so on the right. Two diopters of papilledema was present. At the time of operation, on the fifth hospital day, a left posterior parietal flap was turned and pronounced edema of the brain was observed. This observation along with the ventriculogram was deemed suggestive of a glioblastoma multiforme.

The patient was given demerol on the second hospital day (table 5).

Duguid and Heathcote⁶ reported their observations on cats under urethane and ether anesthesia. They state that "the respiration was invariably affected in any dosage from 1 mg./kg. upwards. With small amounts the result was merely a slight, though prolonged degree of slowing of the rate." These investigators observed that 5 mg. per kilogram doses induced a great reduction in respiratory rate and amplitude along with some irregularity. Single 10 mg. per kilogram doses induced an immediate and permanent cessation of respiration. Also a cumulative effect on respiration was noted following a total dose of 8 mg. per kilogram. The findings of Schaumann,⁷ Barlow⁸ and Gruber, Hart

TABLE 5.—Observations in Case 3

Time in Minutes	Comment	Pulse	Respiration	Blood Pressure
0	Demerol 100 mg. in deltoid.....	96	18	160/100
15	92	18	160/110
30	Feels warm; severe headache.....	82	16	200/140
45	Diaphoresis; sleeping.....	82	14	200/130
60	Irregular respiration; long period of apnea.....	82	4	200/110
75	Pupils small, very sluggish to light	78	16	100/110
90	Pronounced drowsiness.....	82	24	170/100
105	Headache lessened.....	76	24	170/110
120	Irregular respirations persist.....	80	26	165/160
135	Periods of apnea.....	78	18	160/100
150	Still somewhat drowsy.....	78	16	160/100
165	Less drowsy; respirations regular	82	18	165/110
180	Pupils no longer contracted.....	80	24	170/110

and Gruber⁹ confirm the observations on respiratory depression in animals.

Batterman¹ reported 774 cases in which demerol was administered parenterally, and in only 2 instances was any respiratory depression noted. The data obtained from our comparatively small and selected group of cases did not, we feel, warrant the risks of further clinical investigation on patients with intracranial lesions. There was definite respiratory embarrassment in 7 of the 20 patients, and this finding alone should serve as a caution against further use of the drug for patients with intracranial lesions.

Batterman¹ states that he did not observe any change in the pupillary response, while the corneal reflex was diminished or abolished in 80 per cent of the cases. There were, however, 7 instances in this series in which contracted pupils developed after the administration of demerol. Instances of corneal hypalgesia and analgesia were observed.

CONCLUSIONS

Twenty patients with intracranial lesions were given demerol parenterally in therapeutic doses on one or more occasions. In 7 of the 20 patients the respiratory rate fell from the usual rate of 18-22 per minute to 12 per minute or less. In 5 patients respirations fell to 12 per minute, in 1 patient to 8 per minute and in another patient to 4 per minute. Also instances of contracted pupils with sluggish response to light were observed.

It is felt that, from the data which are at hand, demerol should be administered with caution, if at all, to patients with intracranial lesions.

710 West 168th Street, New York 32.

INDUSTRIAL AND DOMESTIC INJURIES
OF THE EYE

C. P. CLARK, M.D.

INDIANAPOLIS

Wounds of the eye vary in type and severity according to the type of agent and the amount of force that produced them. Injuries in industrial and domestic life differ from those that occur in military service in that the forces exerted in their production are of different origin and violence. War injuries occur from high explosive bombs, flying fragments of rock and other debris, chemical gas burns, and from the many other modern engines of warfare. War wounds of the eye are accompanied frequently by injuries to the body trunk, face and skull. Both eyes may be damaged. Many different types of ocular injuries may occur to the same person. If a penetrating wound of the orbit or globe is present, more than one foreign body, usually non-magnetic, may be lodged in the tissue.

Industrial and domestic accidents resulting from other sources of power are on the whole less violent than those that occur in battle. They seldom involve both eyes, are single and are accompanied less frequently by trauma to other parts of the body.

Industrial accidents come from plants that are manufacturing articles with power driven machinery, transportation systems, mines, chemical supply depots and heavy trades. There is ample opportunity for injuries to occur to workmen. The incidence of injury is kept at a minimum by the safety measures instituted for that purpose. Safety engineers, machine guards, protective goggles and the educational safety campaign all contribute to reduce the incidence of industrial injuries. It is obviously impossible to eliminate accidents from the factory entirely, and particularly is this true when there is as large an influx of inexperienced workers as under present conditions.

A certain number of ocular injuries occur in homes and in agriculture. The domestic accidents occur with sharp and pointed articles such as knives and scissors, with various chemicals and with heat. A good illustration of the latter is that associated with improper operation of a pressure cooker. The farm has been mechanized and it is now necessary for the farmer to operate and service equipment that is made with precision and of as many metal alloys as are found in equipment in the factory or on the railroad. The farmer is exposed to ocular injury, and yet it is most unusual for him to possess protective goggles. A short time ago it was my duty to care for a farmer who lost one eye from striking

a chisel with a hammer while repairing a lock on a gate. It is more difficult to conduct an efficient educational safety campaign in the home and on the farm than it is in the factory. The latter offers the greater hazard, but it is much easier there than elsewhere to keep ocular injuries at a minimum.

The first step in consideration of ocular injuries is efficient means to prevent accidents. It is impossible to prevent all injuries of the eyes but the number can be kept at a low percentage compared with the man hours of work.

The second step is prompt and efficient first aid treatment of the injured workman. This may be the copious washing of the eye with tap water by the injured person after a chemical burn. Fellow employees may be taught to give valuable assistance during the time required for the plant physician to reach the scene of the accident. Almost all factories, both large and small, have a first aid station where sterile dressings and medicines are available. The larger factories have physicians in constant attendance.

A greater number employ a registered nurse who administers simple first aid treatment and is under the supervision of a physician on part time duty. First aid treatment should be administered by an experienced person, preferably by a nurse or a physician. The fellow employee may be more dangerous than helpful unless he has been taught by a physician what steps to take. Some years ago I treated a man who was given first aid by a fellow employee for a superficial foreign body injury of the cornea. The foreign body was not removed. Tincture of iodine was mistakenly applied to the eye for mild protein silver.

I do not think that a foreign body that clings to the tissue or is embedded should be removed from the eye by any one other than a physician. He should be provided with proper equipment for illumination and magnification of the eye and should observe strict asepsis in the sterilization of the instruments and in the care of the wound.

Superficial injuries of the eyeball constitute the larger number of all ocular injuries. Each one should be viewed as being potentially dangerous. Bacteria may be introduced into the tissue by the foreign body itself, by the instrument used in the removal of the foreign body or from the lacrimal apparatus or infected conjunctiva before the wound becomes covered with epithelium. For the past several years I have instilled plain cod liver oil whenever there has been a break in the epithelium of the cornea as after the removal of an embedded foreign body, an abrasion or a burn. It has proved to be exceptionally soothing for electric flash burns involving the cornea. The recent addition of a local anesthetic found to be soluble in cod liver oil has enhanced its value.

All simple or superficial injuries of the eye ball should be examined with great care, for what appears to be a minor injury may indicate the presence of an intraocular foreign body.

The care of intraocular foreign body injuries is not considered in this article, but emphasis must be placed on alertness of the ophthalmic surgeon to detect the presence of one after a penetrating injury has occurred.

Injuries of the eyelids in industrial and domestic pursuits are as a rule limited to punctures, contusions, lacerations and burns. Surgical attention to injury of the eyelids requires the application of those principles of surgery employed for other parts of the body. During repair of an interruption of the continuity of the eyelids

attention is given to the direction of the fibers of the orbicularis oculi muscle, the attachment of the levator palpebrae muscle, good apposition to the cut margin of the eyelid and careful reapposition of the tissue when the lacrimal apparatus is involved in the injury. Owing to the vascularity and laxness of the eyelids, much greater edema and discoloration occur than from similar injury to other parts of the body.

The same force that produces a contusion of the eyelid may fracture the bony rim or the walls of the orbit. Examination of the parts should be made by palpation and with the x-rays.

An interruption of the continuity of the eyelid may suggest the presence of an orbital foreign body or an opening into the eyeball. All foreign bodies should be removed from the tissue whenever possible. Some substances are tolerated by the tissue with but little reaction. Foreign bodies in the orbit that do not introduce sepsis or chemical irritation may be permitted to remain if their removal would require extensive surgical trauma. An opening into the eyeball requires prompt careful surgical repair if the eye is to be retained and should be done before repair of the eyelids is undertaken. The use of the sulfonamide compounds both locally and internally for injury of the eyelids is a recent advance. Appropriate serums and antitoxins are to be administered according to the surroundings where the accident took place.

Injuries of the eye are influenced not alone by the force and the agent of their production but also by the atomic protection that nature has provided. The eyeball is protected by the eyelids and the bony walls of the orbit and skull. The orbit may be described roughly as cone shaped with the apex at the optic foramen and the base formed by the eyelids. The contents of the orbit play a part in the function and the control of the eye and act as intermediate protective tissue in that they cushion it against the reception of violent force.

The shape of the eyeball is an example of structural defense. It may be described as a sphere with the cornea being a portion of a smaller sphere superimposed on it in front. This gives the maximum strength that is possible to the walls and protection to the tissue contained within.

The shape and the structure of the eyeball lead to certain types of injury. The weakest places in the wall of the eyeball are at the junction of the cornea with the sclera and at the entrance of the optic nerve into the sclera. With a hard blow a break in the tunic of the eyeball will occur at these places. The shape of the eyeball, being essentially a sphere, leads to injury of the internal structures by contrecoup.

Injury to the intraocular structures without a perforating wound may involve any of them, and the ones most commonly damaged are the iris, the ciliary body, the lens, the retina and the choroid. Laceration of the sphincter muscle of the iris and iridodialysis are common findings following a blow on the anterior portion of the eyeball. Hemorrhage may be extensive. The lens capsule may be interrupted by a sudden sharp blow on the eyeball when sufficient force is exerted to indent the ocular coat enough to rupture the lens capsule. Traumatic cataract is the result. The opacity frequently begins in the posterior cortex. Injury of the retina and choroid may vary from edema to laceration of the tissue or to detachment of the retina.

The care of nonpenetrating injuries of the eyeball is at first symptomatic: sedative drugs for pain, rest in

bed, cold or hot compresses, and atropine to abolish accommodation and to put the iris at rest. Detachment of the retina requires early surgical attention. Traumatic cataract is to be treated surgically according to the development of the opacity and the other conditions of the eye. Secondary glaucoma must be treated according to the general rules for this condition and according to the experience of the surgeon.

Penetrating wounds of the eyeball comprise the more dangerous and destructive group of injuries. The presence of an intraocular foreign body must be considered and when there is a possibility of one being within the eyeball it must be searched for. To overlook one is to invite permanent loss of vision with other and more grave consequences—recurrent uveitis with possible sympathetic ophthalmia of the second eye. When the eyeball is to be retained, the wound is cleansed, prolapsed tissue is cut away and the wound margins are united as accurately as possible with fine sutures. Laceration of the cornea is protected by some form of sliding conjunctival flap until the wound of the cornea has united, and then the flap returns to its original site. Prolapse of the ciliary body and choroid never should be treated by removal of the prolapsed tissue. An injury through the zone of the ciliary body, particularly with prolapse of tissue, is ideal for the production of sympathetic ophthalmia. When the eyeball has been damaged so severely that there is no prospect of retaining useful vision, enucleation should be done at once. It is more conservative to remove a severely damaged eyeball than it is to retain one and invite sympathetic ophthalmia which may mean blindness in both eyes. Care and judgment must be exercised by the surgeon when a decision is made concerning enucleation of an injured eyeball. For the injured eyeball not removed, careful medical attention and nursing are necessary.

SUMMARY

1. The prevention of ocular injuries commands an important place in industry, agriculture and the home.
2. Efficient first aid treatment is important in reducing the loss of man hours of work, in relieving the suffering associated with the injury and, most important of all, in retaining useful vision of the injured eye.
3. Penetrating and nonpenetrating wounds are treated according to the rules that have been proved best by years of experience of the medical profession.
4. Particular care should be taken to avoid sympathetic ophthalmia when there has been an injury of the uveal tract, especially of the ciliary body.

23 East Ohio Street.

ABSTRACT OF DISCUSSION

DR. WILLIAM F. HOLZER, Worcester, Mass.: In my community, where industries are essentially machine tool, abrasive machinery, i. e. grinding wheels, rolled steel and wire drawing, we do not encounter the severe mutilating wounds common to mine accidents or munition plants explosions. Most injuries are foreign bodies in the cornea or abrasions of the cornea. The air hose in cleaning casting is responsible for a number of injuries, as the small chips are blown in the eyes around the glasses or under the side shields. Occasionally a grinding wheel will break, inflicting more serious injury. Our practice is to remove the foreign body, curet the cornea thoroughly, cauterize with 95 per cent phenol and leave the eye uncovered. Sulfathiazole (5 per cent ointment) is applied in the lower cul-de-sac and a tube of 1 per cent phenacaine hydrochloride and epinephrine 1:50,000 ointment dispensed, to be used every hour or two as required. Atropine is not used, as the accommodation is disturbed long after the corneal wound has healed and the workman finds it difficult to do his work well, particularly if

he is doing precision work. More serious wounds are treated as outlined by Dr. Clark. As to domestic injuries, we see the ordinary incised wounds of the cornea and sclera caused by scissors, and knife wounds by cutting knotted shoe laces or string on bundles. A rather common injury is a corneal abrasion caused by infants' fingernails. These may be extensive and very painful; usually phenacaine ointment and a pad will facilitate healing. Another not uncommon domestic injury is that caused by the BB shot. In my experience most of these are extraocular, i. e. in the lids, under the conjunctiva or passing around the sclera rather than penetrating. If accessible they are removed, but if removal is likely to produce considerable trauma they are left in situ. X-ray examination should be made and the patient or parents advised that the foreign body has not been removed. This avoids legal complications. If any foreign body cannot be removed with a cotton applicator by a nurse, the patient should be referred to a physician, and any person with a foreign body in the pupillary area should be referred to an ophthalmologist. The use of safety goggles should be made obligatory in all hazardous occupations and neglect to wear them punishable by lay off periods or discharge for frequent violations. The presence of an intraocular foreign body should not be overlooked, particularly with a history of a hammering operation. In such cases an x-ray examination should always be made to rule out the presence of a foreign body and to avoid future embarrassment.

DR. HUGO L. BAIR, Rochester, Minn.: A common error is the failure to remove early enough a blood clot that fills the anterior chamber following contusion of an eye. Many such eyes have been lost owing to hematogenous infiltration of the cornea and secondary glaucoma. If, within a day after the injury, clear aqueous cannot be seen above the blood in the anterior chamber, it is wise to open the anterior chamber and wash out the blood and remove the clot. It is inadvisable to do this immediately after the contusion because of the likelihood that the source of the bleeding has not become well closed and that further hemorrhage may follow sudden lowering of intraocular pressure. The immediate treatment of such contusions should be to put the patient at absolute rest in bed with both eyes bandaged. I prefer to use neither atropine nor miotics at first, relying simply on rest in bed and the complete bandaging of both eyes to keep the injured eye internally and externally at rest. There is overuse of the conjunctival flap for penetrating lacerations of the cornea. Although once a staunch user of it, I recently have considered it to be an unnecessary evil and have abandoned its use in such cases. Preparation of a conjunctival flap causes considerable additional trauma to and subsequent reaction in the already injured eye. It prevents satisfactory observation of the site of the wound and may conceal the development of hypopyon, iridocyclitis or other intraocular complications of the injury. Along the margins of the flap on the cornea, mucus and debris usually collect to the detriment of the healing processes. With large lacerations of the cornea, the tension exerted by a flap may cause inversion and improper apposition of the edges of the wound. With ragged or infected corneal wounds, adhesions of the flap to the healing wound frequently occur, causing dense leukomas and much corneal irregularity. The larger corneal lacerations should be closed with corneal sutures approximately $\frac{1}{4}$ inch apart. This does not make such a tight closure that aqueous cannot seep out a bit between the edges of the wound, which I believe to be desirable, and yet it keeps the edges of the wound in good enough apposition for proper healing. Usually with corneal wounds of about $\frac{3}{8}$ inch length or less, sutures are not necessary.

DR. EDWARD W. GRIFFEY, Houston, Texas: The microscopic appearance of the fully developed reaction to flash burns of the eye after exposure to the welder's arc is characteristic. In the cornea initially there is nuclear chromatolysis associated with a swelling and edema of the cytoplasm. Thereafter acidophil staining becomes evident in the nucleus, which progresses to the formation of highly refractive red granules within it; these coalesce into discrete "inclusion bodies," which may even-

tually replace the whole of the nucleus. Finally the inclusions may be extruded from the nucleus into the cytoplasm and thereafter the cell dies; it is desquamated if it is a superficial one. The clinical course of such an exposure is typical. Early there is a latent period during which time no effects are visible. Between the latent period and the beginning of the acute symptoms, when the corneal edema is obvious and typical halos are most evident in the human subject, the cornea becomes practically anesthetic. The latent period varies in length inversely as the severity of exposure, averaging from eight to twelve hours. At the end of this time there is a rapid onset of a severe, sharp, continuous ocular pain associated with profuse lacrimation, photophobia and later blepharospasm. At this time the cornea shows a slight irregularity of its reflex and a stippling of its surface, which takes on stain with fluorescein. Even before the onset of corneal pain the patient may experience a pricking sensation about the eye, may see halos about lights (due to corneal edema), and there is seen an erythema of the skin of the lids on the side involved. The clinical picture is at its height in thirty-six to forty-eight hours after irradiation. Thereafter it gradually clears up until, four or five days later, the cornea becomes clear again, the conjunctival injection dies down and the eye becomes normal in eight to ten days. A simple and effective remedy, which in the early initial phase amounts to a good prophylaxis, consists in the use of epinephrine. That is, if three successive instillations of 1:1,000 epinephrine are made at five minute intervals shortly after the onset of ocular pain following flash burn and before objective findings are too obvious, the large majority of patients gain prompt relief and can return to work immediately. The severely burned will require 0.5 per cent pontocaine or 1 per cent holocaine.

DR. ALBERT C. SNELL, Rochester, N. Y.: In industry adequate provisions for rendering such aid should be available in every plant both large and small. These provisions should include proper equipment and supplies, also definite written instructions which are to be followed by the available personnel. Such equipment, supplies and instructions are almost entirely lacking in the small industrial plants; hence the greater relative loss of vision in these plants and the need for better care. The only exception which I wish to take is to the statement that "prolapse of the ciliary body and choroid never should be treated by removal of the prolapsed tissue." Dr. Clark does well to warn of the possibility of sympathetic ophthalmia in these types of injury. However, in my opinion small or medium sized prolapsed parts of the ciliary should be amputated thoroughly. I would also institute sulfonamide therapy together with atropine and antiseptics. But one should always be alert to the possibility of sympathetic involvement! Some of these injured eyes can be saved and should be when vision has not been severely damaged. Since the first week following these injuries is free from the danger of sympathetic ophthalmia, these injured eyes may be kept under observation, at least during this time, without unwarranted risk. In minor degrees of prolapse of the choroid, usually with some vitreous, amputation should be done and prophylactic treatment employed. This can be done without much danger of sympathetic ophthalmia. However, extensive prolapses and a blind eye suggest removal of the eye. Atropine should not be instilled in every injured eye, especially in superficial foreign body injuries—a practice which is commonly followed by first aid personnel. This practice causes much unnecessary lost time for employees. The use of atropine should be left to the ophthalmologist. There is need of a better ophthalmic service in most industrial plants.

DR. C. P. CLARK, Indianapolis: The subject can be summarized briefly: an aggressive educational campaign to prevent accidents where they are most likely to occur, prompt and efficient emergency care for the injured, and employment of good ophthalmic surgical practices for those persons more seriously injured. The methods of accomplishing these aims may vary according to the locality and the facilities that are available.

Clinical Notes, Suggestions and New Instruments

GASTROJEJUNAL HEMORRHAGE FOLLOWING GASTROENTEROSTOMY FOR HYPERTROPHIC PYLORIC STENOSIS OF INFANCY

LIEUTENANT COMMANDER G. ARNOLD STEVENS (MC), U.S.N.R.
AND WILLIAM C. BOECK, M.D., LOS ANGELES

Prior to the introduction of the Rammstedt operation, hypertrophic pyloric stenosis was treated surgically by gastroenterostomy. Although the newer procedure, which has since been universally adopted, was first described by Rammstedt in 1912, certain surgeons persisted for some time in making gastroenterostomies on infants with congenital pyloric stenosis.

To our knowledge 4 cases have been reported in medical literature because of bleeding incident to gastrojejunal ulcer following gastroenterostomy for hypertrophic pyloric stenosis. The ages of these patients at the time they presented themselves for definitive surgery ranged from 22 to 30 years. The first case was reported in 1940 by Fowler and Hanson¹ and treatment was taking down the gastroenterostomy and making a conservative type of pyloroplasty. In 1941 Waltman Walters² reported 3 cases in which he took down the gastroenterostomy and made the Billroth I type of anastomosis. So far as we have been able to ascertain, all 4 of these patients have remained well following the final surgical procedures.

We add 5 cases to those previously reported (4 through the courtesy of Waltman Walters,³ Edward J. Donovan⁴ and John Ruddock⁵ and 1 of our own). One year ago Walters took down the gastroenterostomy and made a Billroth I anastomosis on a young man who had previously been operated on for perforation of a gastrojejunal ulcer by Donovan, with a result which has been satisfactory to date. Donovan also made a Billroth I resection and took down the gastroenterostomy on a man aged 29 for a large bleeding jejunal ulcer following gastroenterostomy performed at 6 weeks of age for hypertrophic pyloric stenosis. Donovan stated to us that "the pylorus was exactly like those found in cases operated on in infancy." Ruddock has seen 3 cases of hypertrophic pyloric stenosis in one family. Two brothers (26 and 28 years old) had gastroenterostomy performed in infancy. Both of these began to bleed at the age of 24 years. The one 28 years old received x-ray therapy less than two years ago and has not bled since. The other (26 years old) also had x-ray therapy and has since had a recent hemorrhage. X-ray examination revealed partial duodenal obstruction in both of these cases. The sister had a Rammstedt operation. She has had no bleeding and has been clinically well.

The case we report differs from the others in two respects. In addition to the taking down of the gastroenterostomy a radical type of pyloroplasty was effected and a segment of the jejunum containing four ulcers, one of which was actively bleeding, was removed.

REPORT OF CASE

A white man aged 31 was admitted to the hospital by one of us (Boeck) with a diagnosis of hemorrhage probably incident to gastrojejunal ulcer. Gastroenterostomy had been performed when he was 6 weeks old for hypertrophic pyloric stenosis. At the age of 19 years his first hemorrhage occurred. At this time he vomited "coffee ground" material and had "tarry" stools. He stated that the attending doctor told his family that

he was in "shock" as a result of severe hemorrhage of the stomach. All in all, nine hemorrhages occurred during a twelve year period, the last of which was on the date of his admission to the hospital. The shortest period between hemorrhages was one month. The longest period was two and one-half years. In 1938 gastric analysis at the Presbyterian Hospital of Pittsburgh showed total acids 36, free acids 24 and loosely combined acids 12. About two months before the onset of the last hemorrhage x-ray examinations showed some pyloric obstruction but were otherwise negative. Gastroscoy did not reveal gastrojejunal ulcer.

After conservative medical treatment for one week in the hospital the patient persisted to bleed, so it was felt safer to intervene surgically. The patient was given 1,000 cc. of whole blood by transfusion immediately before operation, after which the blood pressure was 110 systolic, 60 diastolic. The blood count at this time showed 3,800,000 red cells, 10,000 white cells and hemoglobin 65 per cent. All other routine laboratory tests were negative.

Operation was performed by one of us (Stevens). The gastroenterostomy was taken down and a segment of jejunum was removed containing a diverticulum at the suture line and four jejunal ulcers. The largest of these contained an actively bleeding vessel. The opening in the stomach was closed and intestinal continuity was reestablished by end to end anastomosis of the jejunum. Because of partial obstruction caused by the hypertrophied musculature of the pyloric region, a radical type of Judd pyloroplasty was made, the wedge on each side being excised far posteriorly. This left but a small section of gastroduodenal tissue to serve as an anchor for the suture line. The postoperative convalescence was uneventful. The patient was dismissed from the hospital on the ninth postoperative day. He has been well since (one and one-half years).

PATHOLOGY

The diagnosis made by the pathologist was multiple ulcers of the jejunum, acute and chronic, with one diverticulum.

The specimen consisted of a section of jejunum including the gastrojejunal suture line. Protruding externally from the posterior suture line was a diverticulum 8 mm. deep with a base 5 mm. in diameter. There were four jejunal ulcers, the largest of which was 8 mm. in diameter and the smallest 5 mm. in

Fig. 1.—A, section of pylorus removed; B, reconstructed pyloric region; C, closure of defect in stomach; D, excised jejunum showing four small ulcers; E, jejunal continuity reestablished by end to end anastomosis.

diameter. Two of the ulcers appeared acute. The larger was deep and contained an open vessel, which was apparently the spurting artery seen as the jejunum was opened at operation. Two of the ulcers appeared chronic and were covered with a gray base, apparently scar tissue. The bowel wall, corresponding to the larger of these, was thinned out so that it produced a false diverticulum.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writers and are not to be considered as reflecting the policies of the Navy Department.

2. Walters, Waltman: Partial Gastroenterostomy (Billroth I) for Hemorrhagic Gastrojejunitis Following Pyloric Stenosis, *Proc. Staff Meet., Mayo Clin.* 16: 321 (May 21) 1941.

3. Walters, Waltman: Personal communication to the authors.

4. Donovan, Edward J.: Personal communication to the authors.

5. Ruddock, John: Personal communication to the authors.

Histologic sections through the acute ulcers showed absence of the mucosa with congestion of the submucosa and invasion by polymorphonuclears and lymphocytes. Section through the chronic ulcers showed absence of mucosa and submucosa and replacement with connective tissue.

COMMENT

The cases reviewed in this report present certain factors in common. In all gastroenterostomy was performed in infancy for hypertrophic pyloric stenosis. All showed a partial persistence of the pyloric defect. In all there were repeated hemorrhages incident to jejunal erosion or ulceration and all were cured by the combined surgical procedures of taking down the gastroenterostomy and correction of the partial pyloric obstruction. None of the patients had gastric or duodenal ulcer.

Fig 2—A, excised gastrojejunal segment showing hypertrophied musculature of the pyloric region; B, gastrojejunal defect following excision of A; C, reconstructed pyloric outlet.

There were several interesting features in the report of the cases of Walters. In 2 of these pyloroplasty had been performed elsewhere and in 2 cases perforating jejunal ulcers had been excised with simple closure of the jejunum. In none of these was cure effected until the gastroenterostomy had been subsequently taken down. Reduction of gastric acidity was noted by Walters in 3 cases after taking down the gastroenterostomy and making a Billroth I type of gastric resection. In 1 of his cases relative achlorhydria was present before surgery.

In our case also relatively low acids existed before the operation was performed. Thus 2 cases of the small group reported showed relatively low gastric acids before operation, yet the same pathologic condition developed as in those with normal or high acids. Is it then reasonable to place too much importance on gastric acidity as a major factor in the pathogenesis of gastrojejunal ulcer in this type of case? It is true that one of the patients seen by Ruddock received x-ray therapy in the hope of preventing further ulcer formation by lowering gastric acidity. This patient has not bled for almost two years. On the other hand, our patient went as long as two and one-half years between hemorrhages and he had received no x-ray therapy. It seems reasonable to assume that the patient who did have x-ray treatment will probably bleed again.

Gastroscopy between hemorrhages on our patient was negative. It therefore appears that the jejunal erosions and ulcerations tend to heal intermittently and that the healing is only temporary.

Since our patient showed relatively low acids, it seemed to us unnecessary to subject him to the added risk of any type of gastric resection. Therefore the obstruction was treated by pyloric reconstruction.

All of the patients have remained cured after the gastroenterostomy was taken down, with adequate correction of the pyloric defect, regardless of whether the procedure of gastric resection or pyloroplasty was used.

More time must elapse before the relative merit of these procedures can be evaluated conclusively. It does seem reasonable to conclude, however, that any combination of surgical procedures must include taking down the gastroenterostomy in order to effect a cure of this condition.

Committee on American Health Resorts

THE COMMITTEE ON AMERICAN HEALTH RESORTS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT ON THE ACCEPTANCE OF THE TORBETT CLINIC AND HOSPITAL. A COPY OF THE RULES ON WHICH THE COMMITTEE BASES ITS ACTION WILL BE SENT ON REQUEST.

W. W. BAUER, M.D.

TORBETT CLINIC AND HOSPITAL, MARLIN, TEXAS, ACCEPTABLE FOR LISTING BY COMMITTEE ON AMERICAN HEALTH RESORTS

The Torbett Clinic and Hospital, Marlin, Texas, applied for listing by the Committee on American Health Resorts of the American Medical Association. The Committee has been furnished with all the information required under its rules, including copies of advertising and promotional material, and a report on an inspection by a Committee representative. The submitted information and the report indicate that the institution is operated in accordance with the rules of the Committee. The distribution of advertising material not in accordance with these rules has been discontinued.

The Committee on American Health Resorts is satisfied that Torbett Clinic and Hospital is being operated in accordance with the rules of the Committee and has placed this institution on the list of American Health Resorts complying with the Committee rules for a period of one year beginning Nov. 1, 1943. This listing may be continued for three year periods if the listed institution continues to comply with the rules.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

HOWARD A. CARTER, Secretary

DISINFECTAIRE ULTRAVIOLET GERMICIDAL UNITS

(Hospital Operating Room, Nursery and Ward Models)
ACCEPTABLE

Manufacturer: Ait Metal Company, 1814 East 40th Street, Cleveland

The Disinfectaire Ultraviolet Germicidal Units Nos. 2543, 2545 and 2607 are designed to irradiate the upper air of a room with ultraviolet radiation for disinfecting purposes. The fixtures are said to be so designed that when correctly installed there is little or no direct irradiation of individuals. Unit No. 2543 is described as a "Standard Indirect Type," Unit No. 2545 a "Bactericidal Barrier Direct-Indirect Type," and Unit No. 2607 is termed a "Suspended Bactericidal Barrier Direct-Indirect Type."

The source of irradiation in each of the models is the General Electric 30 watt germicidal lamp. This lamp is described in the Council report "Ultraviolet Lamps for Disinfecting Purposes."¹ Careful consideration should be given to the introductory statement of this report because it presents detailed information about the limited conditions under which the units may be employed efficaciously.

In the aforementioned report it is pointed out that Council acceptance is limited to ultraviolet disinfecting lamps designed for installation in hospital nurseries, hospital wards and operating rooms where the radiation has been found useful as an adjunct to other measures of asepsis. Ultraviolet lamps are not accepted for disinfecting air in schools, waiting rooms, public gathering places and large halls because satisfactory evidence is not available to warrant their acceptance for such purposes. For the same reason the units are not accepted for disinfecting solids such as drinking cups, combs, brushes, shaving utensils, toilet seats and shoes.

The Council voted to accept the Disinfectaire Ultraviolet Germicidal Units Nos. 2543, 2545 and 2607 for inclusion in its list of accepted devices.

1. Council on Physical Therapy: Ultraviolet Lamps for Disinfecting Purposes. J. A. M. A. 122:62 (Sept. 11) 1947.

SATURDAY, JANUARY 15, 1944

THE PHYSICIAN AND THE FOURTH WAR LOAN

Nervi belli pecunia infinita (The sinews of war are infinite money).—Cicero.

On January 18, throughout the nation, the 4th War Loan campaign begins. Fourteen billion dollars is the goal that has been set; five and one-half billion of this sum is to be secured from individual purchasers. The physician, as an individual, will be approached through his bank, his clubs, his hospital, his university and medical school and his home. The state and county medical societies may cooperate, if they wish, by making an organized approach to their membership, assigning quotas to individual physicians and establishing special war loan committees to make certain that each physician hears personally of the need for his individual investment in this war loan. No doubt many county and state medical societies will wish to engage in the 4th war loan campaign as an organizational effort; they may welcome speakers to address their sessions. Certainly every leader of American medicine will wish to do the most that he can to aid in achieving the goals that have been established.

One third of the active medical profession have sought and accepted commissions in the armed forces; the physicians of our country not only "Back the Attack" but also play their part in it. Physicians who remain at home are participating in the war to the limits of their physical strength. They work on Selective Service boards, in the activities of health departments, in civilian defense, in the care of the injured in industry, in the campaigns against epidemics and disease. They are maintaining the high tradition of the profession. Since the very nature of their occupation makes difficult an organized approach, such as is made to workers in businesses, industries, trades or other occupational classes, they will quite certainly subscribe as individuals for war bonds to the fullest extent that their finances permit.

To carry on war three things are necessary: money, money, and yet more money.—Trivulzio's message to King Louis XII.

The glorious victories of our troops, wherever they are engaged, give to every American the thrill that comes in greatest measure to those who participate in the victory. The message of General Clark to General Kirk extolling the accomplishments of the medical corps at Salerno, the magnificent statistics of recovery of the wounded, of the prevention and cure of infectious diseases, of health and nutrition arouse a pardonable pride in each of us. The physician's responsibilities as a leader in his community, as a citizen and as a teacher place on him a special responsibility in the nationwide drive for the 4th War Loan. His patients will respect him all the more when he urges on each of them his patriotic duty and when he tells them the extent to which he himself has subscribed. Some years ago in Newark, N. J., when funds were being raised for the building of a hospital, Cardinal Walsh climaxed the appeal, saying "Look into your hearts; think of the most that you can subscribe and then double it!" Our leaders in this 4th War Loan drive have set the quota as "at least one extra \$100 bond for every person with income." The peril of inflation may be met to some extent if even that hundred dollars is siphoned away from the explosive excess purchasing power that now resides in many an American purse.

War is a matter not so much of arms as of expenditure, through which arms may be made of service.—Thucydides.

American production has been a most important factor in the success of the United Nations. We glory in the sufficiency of armament, in the amplitude of nourishment, in the quantity and quality of our medical supplies. Here are a few costs submitted by government sources:

Collecting station equipped to give 600 battle casualties emergency treatment or a mobile surgical unit—a truck equipped to provide special surgical care for serious casualties..	\$ 4,200
Clearing station providing temporary care for the wounded	30,000
Ambulance plane for transportation of seriously wounded	110,000
General hospital of 1,000 beds.....	300,000

As an aid to the bond campaign, organizations which sell \$110,000 worth of bonds within their time limit may name "their" ambulance planes, and groups buying ambulances or an ambulance train have the privilege of placing a plaque on "their" equipment. Thus the hospital at home may have a namesake in service at the front.

The securities for the 4th War Loan are designed to encourage long time investment of savings and current income. Money thus invested serves many objectives; primarily, however, it is the very sinews of war, the weapons and munitions of combat, the food to sustain the fighter, the medical supplies for the care of

the wounded, the clothing and the housing facilities of troops in training and at the front. And as the war moves on to its conclusion in triumph these funds serve not only to "Back the Attack" but to "Bring Them Back."

HUMAN SERUM COMPLEMENT

Ecker and his co-workers¹ of the Institute of Pathology, Western Reserve University, report the fractionation of human serum complement into four essential components. Originally Bordet, Ehrlich and others assumed that "complement" or "alexin" is a single chemical entity, a panimmunizing enzyme that requires specific antibodies for its lytic action. This concept was soon challenged by Ferrata,² who showed that if guinea pig serum was separated into a globulin and albumin fraction neither fraction contained complement but that the original complement titer could be restored by combining the two fractions. Complement thus became an albumin-globulin complex, the terms "end piece" and "mid piece" being applied to the two fractions, so that complement was still conceived to be a single chemical entity.

In 1914 Coca³ suggested that there was a third essential factor in guinea pig complement, which could be specifically absorbed on yeast or on insoluble yeast carbohydrate ("zymosan"). This third component is believed to be a lipid. A fourth essential component was afterward discovered in guinea pig complement,⁴ a heat stable fraction specifically inactivated by dilute ammonium hydroxide or by hydrazine. This fourth component contains a reactive carbonyl group, which presumably accounts for this inactivation.

A simplified terminology⁵ for the four essential components of guinea pig complement is now in general use, the symbols C'1, C'2, C'3 and C'4 being substituted for the "mid piece," "end piece," "third component" and "fourth component" respectively of the older nomenclature. When guinea pig complement exerts its hemolytic, bacteriolytic or bactericidal activity, C'4, C'2 and varying amounts of C'1 combine with the antibody-antigen complex (e. g. sensitized bacteria), the essential enzyme (C'3) remaining unbound. A deficiency of any one of the four factors inactivates guinea pig complement. Thus in the hereditary complement deficiency of certain strains of guinea pigs there is a hereditary lack of C'3, the three other components being apparently normal.⁶ An excess of C'1 in guinea pig serum is anticomplementary.

Applying the same technic to human serum, the Cleveland pathologists found that human complement

also is a complex of at least four essential components, only one of which (C'3) is identical with the homologous factor in guinea pig serum. Another factor (C'1) is mutually interchangeable with the homologous component of cow or sheep serum. In human serum also the bactericidal or hemolytic action is destroyed by inactivation of any one of the four components. Of particular interest is their finding that a serum fraction which contains only C'2, C'3 and C'4 has the power of "fortifying" normal human complement.

Study of human complement variations under pathologic conditions now in progress in the Cleveland laboratory may lead to new or improved serodiagnostic methods or to successful methods of correcting, fortifying or maximizing normal or pathologic human complement. The latter might be of wide clinical interest, particularly in connection with future methods of fractional plasma transfusion.

THE WAR AND THE DISTRIBUTION OF PHYSICIANS

The effect of the war on the distribution of physicians has recently been discussed by Perrott and Davis.¹ These investigators of the United States Public Health Service report a survey of the changes in the medical manpower picture. Moreover, they attempt an estimate of the changes to take place during the next few years.

The war has withdrawn about one third of the active practitioners of medicine in the United States. The rate of decrease in the number of civilian physicians from Jan. 1, 1942 to the present time has been precipitous. There were more than 130,000 active private practitioners on Jan. 1, 1942; there will be only about 85,000 at the end of 1943. The recruiting of practicing physicians has already diminished greatly; the armed forces will obtain additional medical officers from among the graduating medical students. The services expect to take 80 per cent of all medical graduates; the number entering civilian practice will no longer fully replace those who die or retire. Consequently Perrott and Davis predict an annual net loss of about 2,100 for the period following Jan. 1, 1944.

The rate of attrition, the authors predict, will tend to be most severe in the states which were medically poor before the war: these states generally have a high proportion of older graduates and receive an unduly low proportion of new medical graduates. New York, with about 10 per cent of the country's population, receives nearly 18 per cent of the new physicians; Alabama, with about 2 per cent of the population, receives but one third of 1 per cent. Twenty-eight states with a combined population of 54,500,000 are expected to have more than 1,500 persons per physician

by Jan. 1, 1944, and seven of these states, with 13,500,000 population, will have more than 2,000. During the past twenty years² there has been a trend for the states rich in physicians to become richer and for the states poor in physicians to become poorer, largely because of the preference of new graduates to locate in the states which most encourage medical practice.

The analysis by these officers of the United States Public Health Service serves to indicate certain aspects of the distribution of physicians, to which attention may well be directed in postwar planning for medical services. The situation described need not necessarily demand a revolution in medical education or medical practice for its correction. Improvement in the supply of hospital and laboratory facilities may promptly have a salutary effect.

Current Comment

A REMARKABLE EPIDEMIC OF INFECTIOUS MONONUCLEOSIS

Halerow, Owen and Rodger¹ describe an outbreak of infectious mononucleosis with unusual features in a hospital and surrounding districts in August 1942. Among a selected population, mainly young soldiers, the main age incidence of the disease concerned those from 20 to 45 years of age; the incubation period seemed to vary from five to ten days. Efforts to trace case to case transmission did not give satisfactory results. On August 5 a woman aged 25 was admitted to the hospital with a typical attack. In a few days 4 other patients were admitted. Soon a physician who had taken care of the first patient, then other members of the medical and surgical staffs and many patients in the hospital contracted the disease. Now a special study was made of all the other patients and members of the medical and nursing staffs, in all 296 persons, of whom 290 presented evidences of infection either clinical (125) or hematoserologic without clinical manifestations (165). The hospital was closed to new patients on August 25. Relatives of the staffs living outside the hospital also presented clinical evidences of mononucleosis, and studies of people in the vicinity revealed many cases of latent or mild infection; but of 20 persons living 35 miles distant, none had clinical or hematoserologic indications of the disease. These and other facts are interpreted as indicating a well localized epidemic of a mild form of mononucleosis of unusual infectivity. White blood counts and tests of the serum for heterophilic antibody (agglutinin for sheep corpuscles) gave results of decisive significance in these studies. In the absence of such tests the cases outside the hospital undoubtedly would have been

"regarded as influenza, gastroenteritis, etc." In view of the reports of false positive tests for syphilis in infectious mononucleosis, tests for syphilis were made in many of the cases in the hospital; the results were uniformly negative. The other unusual features of the epidemic are the extensive infection in adults and the frequent hematoserologic evidences of infectious mononucleosis without any of the usual clinical manifestations.

DYSGERMINOMA OF THE TESTIS

Dysgerminoma (seminoma) is the most common tumor of the testis. In nature and structure it is a cellular, undifferentiated carcinoma arising from cells in the testicular tubules. The tumor occurs most frequently in the fourth decade; its growth may be rapid or slow. Metastasis, mostly in the abdomino-aortic lymph nodes, followed later by generalization, may occur early, sometimes even before the primary growth is detected. The best treatment of testicular cancer at present seems to be orchiectomy as promptly as possible, even if metastasis has occurred, followed by radiotherapy directed against possible or actual metastasis. The effect of proper roentgen treatment on metastases of dysgerminoma may be so prompt as to have diagnostic significance. The results of orchiectomy and radiotherapy in 103 cases of dysgerminoma treated at the Mayo Clinic under fairly uniform conditions are noteworthy.¹ Of the patients who received roentgen treatment "71.1 per cent lived five or more years. Of those patients who did not receive roentgen treatment the survival rate was 58.8 per cent for the same length of time." Other forms of testicular cancer treated in the same general way did not do by far so well. The demonstration that the metastases of this tumor are susceptible to the roentgen ray marks an advance in the radiotherapy of cancer. As in other forms of curable cancer, early diagnosis and prompt treatment in competent hands hold out the best hope for the cure of dysgerminoma of the testis.

BENJAMIN FRANKLIN'S CONTRIBUTION TO MEDICAL SCIENCE

On January 17 the nation will celebrate the 238th anniversary of the birth of Benjamin Franklin. One of the least known facets of Franklin's multisided nature was his interest in medical science. Although lacking formal medical education, Franklin made important investigations on the common cold and on lead poisoning. Franklin was actively interested in inoculation against smallpox, in debunking mesmerism, in optometry, in heart action and in medical instruments. In view of Franklin's activities in so many other fields of knowledge, it is not surprising that he should have been attracted to medicine and that his genius was apparent there as elsewhere.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeons General of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession.

ARMY

NEW POLICIES GOVERNING DISCHARGES FROM THE ARMED FORCES

The War Department in regulations dated Dec. 15, 1943 has changed the regulations issued in November 1942 regarding discharges from military service, particularly as they relate to tuberculosis, neuropsychiatric disorders and malaria. The new regulations are as follows:

(1) No individual with a disability incurred in line of duty will be discharged on certificate of disability until definitive treatment has been completed, except those having tuberculosis or neuropsychiatric disorders. Types of cases which should be retained for treatment include those requiring skin graft, bone graft, revision of amputation stumps, closure of colostomy, etc.

(2) Individuals unfit for Army service because of neuropsychiatric disturbances will not be retained for definitive treatment but will be discharged, and arrangements will be made for further care by the Veterans' Administration if such is indicated. Exceptions are those individuals with neuropsychiatric conditions incurred incident to the service who, in the opinion of the medical officer, may within a reasonable period be returned to duty within the continental limits of the United States.

(3) Enlisted personnel developing tuberculosis, unless terminal cases, will be transferred to Veterans' Administration facilities and discharged as soon as a definite diagnosis of tuberculosis and disablement for further military service are determined. Exception to this policy may be made in the case of personnel nearing completion of twenty years' service and noncommissioned officers of the first three grades when the prognosis is favorable for a complete recovery and restoration to duty within one year. Such individuals will be transferred to Fitzsimons General Hospital, or other designated Army hospital, for treatment.

(4) Terminal cases and those in which such transfer will endanger the patient's life or recovery will be retained in the service and hospitalized until death ensues or transfer to a Veterans' Administration facility becomes possible.

(5) Individuals will not be separated from the military service solely because of malaria, in the absence of permanently incapacitating residuals or sequelae such as marked splenomegaly or cachexia. Repeated relapses alone will not constitute a cause for separation.

(6) When the enlisted man is to be separated from the service on certificate of disability for discharge, irrespective of line of duty status, and further hospitalization is necessary, he will be transferred to a Veterans' Administration facility and will be discharged.

MANAGEMENT OF CONVALESCENCE FROM MALARIA

Circular Letter No. 197 concerns the management of convalescence from malaria and was issued by the Office of the Surgeon General, Washington, D. C., December 27. Otherwise healthy persons quickly recover from isolated attacks of malaria, and a convalescent period of two weeks is considered ample during which time sufficient rest, a well planned diet and pro-

gressively increasing activity, are usually the only measures necessary. Only when anemia is present is iron required. Patients who have had short intervals between a long series of attacks of malaria sometimes remain depressed and in a debilitated state for an excessively long time. Steps should be taken to aid convalescence in this group of cases. Diets should be planned to be attractive, appetizing and palatable in addition to containing the essential nutrients. Vitamin supplements such as cod liver oil and dried yeast tablets may be taken. The patient should enter a reconditioning program as soon as his condition permits. Activities should be both recreational and useful and should hold the patient's interest and keep him busy, mentally and physically. Boredom or undue fatigue should not be permitted, and the sense of usefulness and responsibility should be aroused and developed.

THE 297TH GENERAL HOSPITAL

The 297th General Hospital, at Banning, Calif., is composed of an affiliated unit from the Cook County Hospital, Chicago. The unit was activated June 10, 1943 at Temple, Texas, arrived at Banning on September 30 and has been established in the theater of operations type buildings with a bed capacity of 1,063. In addition to the usual x-ray service and clinical laboratory facilities the hospital is equipped with a physical therapy department and with basal metabolism and electrocardiographic laboratories. All types of disease or injury incurred by military personnel are admitted to this institution. Col. Francis W. Pruitt is commanding officer, and Major Gordon E. Snyder is executive officer. Other medical officers on the staff are as follows:

MEDICAL SERVICE

Lieut. Col. George F. O'Brien, chief of medical service.	Capt. John L. Bohan.
Major Max Kaplan, assistant chief of medical service.	Capt. John V. Burke.
Major Melvin L. Afremow.	Capt. Charles J. Hillenbrand.
Major John Ashworth.	Capt. Lawrence A. Levitt.
Major Paul L. Bedinger.	Capt. Robert O. Levitt.
Major Emmett D. Wall.	Capt. James W. Pick.
	Capt. Leonard J. Trilling.
	Capt. John S. Zelenik.

SURGICAL SERVICE

Lieut. Col. Chester C. Guy, chief of surgical service.	Capt. Eugene A. Hamilton.
Major Peter A. Nelson, assistant chief of surgical service.	Capt. Frederick J. Leemann.
Major William C. Beck.	Capt. Francis A. Napolilli.
Major Wesley A. Gustafson.	Capt. Henry T. Oleck.
Major Hampar Kelikian.	Capt. Carl K. Solander.
Major Richard A. Perritt.	Capt. William B. Sullivan.
Major John J. Walsh.	Capt. Malcolm C. Todd.
Capt. Nicholas J. Capos.	Capt. Herbert L. Udesky.
	1st Lieut. Edmund R. Donoghue.
	1st Lieut. William H. Walters.

DENTAL SERVICE

Lieut. Col. Joseph L. Uhl, D. C., chief of dental service.	Capt. John B. Davis, D. C.
Capt. Irwin J. Altheim, D. C.	Capt. Wesley M. Kirtz, D. C.
	Capt. Leo Stern, D. C.

LABORATORY SERVICE

Lieut. Col. Alex B. Ragins chief of laboratory service.

X-RAY SERVICE

Major Elbert K. Lewis, chief of x-ray service.	Capt. George W. Smith Jr.
--	---------------------------

**CAPT. MORGAN K. ADAMS RECEIVES
SILVER STAR AWARD**

Capt. Morgan K. Adams, formerly of San Bernardino, Calif., has been awarded the Silver Star for gallantry in action during August 1943. The citation accompanying the award read as follows: "In the vicinity of . . . , Sicily, Captain Adams, Battalion Surgeon, being summoned to attend wounded soldiers in a forward area, subjected to heavy enemy artillery fire all the while, did, with total disregard for his own personal safety, and with shell fragments flying in his immediate vicinity, go to the aid of wounded, administer aid, and evacuate wounded to the rear. Captain Adams's prompt action was instrumental in saving the lives of many injured and reflects great credit on himself and the military service." Dr. Adams graduated from the College of Medical Evangelists, Loma-Linda, Calif., in 1939 and entered the service Nov. 1, 1940.

**TWENTY-EIGHTH CLASS OF MEDICAL
ADMINISTRATIVE CORPS OFFICERS**

The twenty-eighth class of Medical Administrative Corps Officers at the Officer Candidate School, Camp Barkeley, Texas, graduated on December 29. The course was of four months' duration and included medical administration, supply, organization of the army, sanitation, first aid, chemical warfare, tactics, training and logistics. Each candidate was given the opportunity to prove his ability to command troops during the course, and acting company and platoon officers and noncommissioned officers were chosen from the ranks twice each week. Brig. Gen. Roy C. Heflebower, commandant of the school, delivered the graduating address and Capt. Willard E. Thompson, executive officer, administered the oath of office.

ARMY NEWS BRIEFS

A medical history of the war, recording in photographs and drawings new surgical technic and unusual treatment of disease, is being compiled by members of the Museum and Medical Arts Service of the Army Medical Corps in the European theater of operations.

Sergt. Joseph G. Nalepovic, Silver Spring, Md., recently photographed a simplified method of applying plaster casts in the field. He made a series of twelve pictures in which the various stages of preparing and applying the plaster were demonstrated.

Drawings of a case of coloboma were made by Sergt. Clifton B. Potter, Beverly, Mass.

Capt. Ralph D. Reed, Bethesda, Md., formerly a bacteriologist with the United States Public Health Service, with the aid of three photographers and two medical artists has set up an "art gallery" and dark room. He and his staff take motion pictures of any operation or treatment which is valuable for future study by army doctors. Other members of the unit are Sergt. Robert C. Adams Jr., Lumberton, N. C.; Sergt. Howard L. Cradick, Indianapolis, and Corp. Howard Francis, Ridley Park, Pa.

THE RHOADS GENERAL HOSPITAL

The Rhoads General Hospital, Utica, N. Y., was formally dedicated on Oct. 30, 1943. The dedicatory address was delivered by Hon. James M. Mead, United States Senator of the state of New York. At this ceremony the commanding officer of the Rhoads General Hospital, Col. Austin J. Canning, was awarded the Legion of Merit for exceptionally meritorious service during the attack on Pearl Harbor, Dec. 7, 1941.

The Rhoads General Hospital is the standard cantonment type being used by the army during the present war and was named in honor of the late Col. Thomas Leidy Rhoads, who served with distinction in the Medical Corps of the United States Army for more than thirty years, and who served as the personal physician to Presidents Taft and Wilson. For his service in France during the first world war he was awarded the Distinguished Service Medal.

**STUDY REQUIREMENTS OF PERSONNEL
FOR ADMISSION INTO THE
ARMED FORCES**

The following physicians were appointed by the President as members of a commission to study and report on the requirements of personnel for admission into the armed service:

Rear Admiral Ross T. McIntire, Surgeon General of the Navy, Washington, D. C.
Major General Norman Kirk, Surgeon General of the Army, Washington, D. C.
Dr. Alan C. Woods, ophthalmologist in chief, Johns Hopkins Hospital, Baltimore.
Dr. Frank H. Lahey, surgeon in chief, Lahey Clinic, Boston.
Dr. Edward A. Strecker, professor of psychiatry, University of Pennsylvania, West Philadelphia, Pa.

**BRIG. GEN. LEON A. FOX AWARDED
DISTINGUISHED SERVICE MEDAL**

Brig. Gen. Leon A. Fox was awarded the Distinguished Service Medal for "exceptionally meritorious and distinguished service in a position of great responsibility while serving as Health Director for the Caribbean and North Atlantic Engineer Division from Nov. 30, 1940 to Dec. 15, 1942. During this period, in addition to his normal duties as division health director, General Fox was charged with carrying out a health program of great magnitude in connection with construction work in the Caribbean bases, northern ferry routes, ferry routes across Africa, Pan American highway, northwest division, and foreign missions located in Africa, Iran and Iraq. Throughout, General Fox has demonstrated great foresight, energy, organizing ability and inspiring leadership, which have contributed in large part to the successful prosecution of these important projects." Dr. Fox graduated from the University of Cincinnati College of Medicine in 1912, and after serving in the Alabama National Guard he was commissioned in the regular army of the United States. He has also been awarded the Legion of Merit for exceptionally meritorious service as chief health officer, Caribbean Division, Caribbean Defense Command.

**MAJOR NATHAN H. WEXLER RECEIVES
SOLDIER'S MEDAL**

Major Nathan H. Wexler, formerly of Brooklyn and now flight surgeon in a P-38 "The Lightning" fighter unit somewhere in New Guinea, was awarded the Soldier's Medal for "his courageous actions in the caring for wounded personnel during one of the most severe enemy air raids in this theater. This service on his part, in addition to his regular duties of keeping positive check on the physical and mental well-being of every member of his outfit, has earned for him the sincerity of respect of this entire unit." Dr. Wexler graduated from New York University College of Medicine, New York, in 1932 and entered the service in January 1942.

AWARDED LEGION OF MERIT MEDAL

Capt. Oscar L. Entin, formerly of Chicago, was recently awarded the Legion of Merit medal for leading a rescue party through the French Guinea jungle last spring to the wreckage of a plane piloted by Lieut. Tommy Harmon, former All American football player. The citation accompanying the award read as follows: "With no advance notice and less than a half hour wherein to make preparations, Entin accepted the responsibility and carried it through to a successful conclusion, recovering the bodies of all except one member of the airplane's crew and obtaining information helpful in determining the nature of the accident." Dr. Entin graduated from Loyola University School of Medicine, Chicago, in 1936 and entered the service Nov. 20, 1941.

ARMY PERSONAL

The honorary degree of doctor of science was conferred on Brig. Gen. James Stevens Simmons, U. S. Army, chief of the Preventive Medicine Service, Office of the Surgeon General, by the University of Pennsylvania, December 22.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

PHYSICIANS SUBJECT TO EMPLOYMENT STABILIZATION PROGRAM

The War Manpower Commission has recently announced that physicians, dentists, veterinarians, sanitary engineers and nurses who are salaried employees in essential or locally needed activities are hereafter subject to the same provisions of any employment stabilization program as applies to other workers in such activities. Such professional employees may not change their jobs without securing statements of availability from the United States Employment Service or being referred to new jobs by this service. The Employment Service, however, it was emphasized, will make referrals of such employees only after consulting the state chairman of the Procurement and Assignment Service. This procedure, it was explained, will insure referral of these professional workers to jobs in which they can make their most effective contributions to the war effort. On approval of the regional war manpower director, any state director may delegate the duty of referring such employees to new jobs to the state and local offices of the Procurement and Assignment Service.

ARMY AND NAVY DENTAL CORPS

According to C. Willard Camalier, D.D.S., of Washington, D. C., chairman of the American Dental Association's war service committee, 800 more civilian dentists will be drawn from the home front for duty with the Army Dental Corps, and another 1,000 men from dental schools will be commissioned to supplement the present corps of 13,000 dental officers. The Navy has 4,000 dental officers, at least 1 assigned to every ship of cruiser class or larger, and to every tender, hospital ship and transport. Army dentists have been provided with portable equipment, collapsible chairs and foot powered drills and portable sterilizers for use close to combat areas. Army dentists in the service now have a record of 4 million cases admitted to treatment last year. They installed more than 7½ million fillings, and during the month of March 1943 extracted 582,546 teeth. In the same month they replaced 456,783 teeth. In a recent month the Navy Dental Corps installed 50,000 fillings and restorations. Dr. Camalier stated that every effort is being made to insure the dental health of the men in the armed services and to save them pain incident to such infections.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quotas allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, January 1, p. 44)

FLORIDA

Pensacola Hospital, Pensacola. Capacity, 197; admissions, 6,248. Sister Vincent, R.N., Superintendent (interns, residents—mixed).

MICHIGAN

Grace Hospital, Detroit. Capacity, 555; admissions, 16,677. Dr. E. F. Collins, Medical Director (2 interns).

St. Mary's Hospital, Saginaw. Capacity, 387; admissions, 9,429. Sister Electa, R.N., Superintendent (2 interns, 1 resident—mixed).

Saint Joseph's Mercy Hospital, Detroit. Capacity, 225; admissions, 9,500. Sister Mary Camilla, R.N., Superintendent (2 interns and 1 resident—general).

MISSOURI

Christian Hospital, St. Louis. Capacity, 145; admissions, 2,760. Miss Agnes Heman, R.N., Superintendent (residents—mixed).

TEXAS

City-County Hospital, Fort Worth. Capacity, 186; admissions, 5,598. Mr. A. C. Seawell, Administrator (assistant resident).

WISCONSIN

St. Luke's Hospital, Milwaukee. Capacity, 135; admissions, 4,644. Mr. M. E. Knisely, Superintendent (1 intern).

NATIONAL REGISTRATION FOR NURSES POSTPONED

The Directing Board of the Procurement and Assignment Service issued form 328, dated January 1, to state chairmen for nurses, stating that the national registration of nurses planned for the week of February 7 has been postponed indefinitely, owing to circumstances beyond the control of the War Manpower Commission. States are requested not to hold a registration of their own until the status of the national registration is determined. It was also stated that a draft of nurses for military service is not contemplated.

MISCELLANEOUS

MEDICAL AND SURGICAL RELIEF COMMITTEE OF AMERICA

The Medical and Surgical Relief Committee of America, 420 Lexington Avenue, New York City, donated during December 1943 medical equipment valued at \$1,715 to one crashboat squadron and four motor torpedo boat squadrons. The committee's gift is part of a current project that to date has distributed emergency medical kits to more than 900 subchasers, destroyer escorts, gunboats, mine sweepers and patrol boats, in addition to supplying battle dressing station equipment to battleships, cruisers and destroyers. A philanthropic organization dedicated to medical aid for the armed and civilian forces of the United Nations, the Medical and Surgical Relief Committee is conducted by a nationwide group of physicians and surgeons, of which Dr. Joseph P. Hoguet is medical director.

INTER-AMERICAN NURSES TRAINING PROGRAM

The United States is cooperating with eighteen of the other American republics in an inter-American health and sanitation program, which has increased the demand for nurses. Training of additional personnel is being carried out mainly under special inter-American cooperative health services organized in the other American republics. Dr. Janet Welch Mackie, who is with the health and sanitation division of the Institute

of Inter-American Affairs, Washington, D. C., has recently surveyed the nursing needs of the other Americas. She recently returned from Bolivia, where she assisted the Servicio Cooperativo Inter-Americano de Salud Publica in developing a child health and nurses training program. In reporting on the work, Dr. Mackie said "It is realized not only by the medical staffs of the servicios but by the local medical authorities that one of the greatest handicaps to the development of public health activities is the lack of professionally trained nurses, particularly public health nurses. The servicios, therefore, have attempted to promote nursing education to meet the needs as rapidly as possible. The training of public health nurses is a direct requirement to supply personnel for health centers now being established in many places in Latin America."

A fellowship plan for postgraduate study in the United States in nursing administration, public health and nursing education is another phase of the inter-American program. Seven nurses from Brazil, Bolivia and Peru hold one year nursing fellowships for study in the United States.

WARTIME GRADUATE MEDICAL MEETINGS

Comdr. Harry P. Schenck, 1912 Spruce Street, Philadelphia will act as national consultant in otolaryngology for the Wartime Graduate Medical Meetings. At present he is working on the selection of men for the National Faculty in this specialty.

ORGANIZATION SECTION

FORTIETH ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

The sessions of the Congress on Monday, February 14, will be under the auspices of the Council on Medical Education and Hospitals.

At the morning meeting Dr. Ray Lyman Wilbur will present a report for the Council on Medical Education and Hospitals and will preside over a symposium on problems of postwar medical education. The following topics will be included: "The Medical School Program," "Hospital Training of Medical Graduates," "Readjustments of Returning Medical Officers," "The Distribution of Medical Care" and "Postwar Financing of Higher Education." Participants will include Dr. Harold S. Diehl, dean of the Medical Sciences of the University of Minnesota, Dr. Samuel Soskin, medical director and dean of postgraduate education of the Michael Reese Hospital, Chicago, Dr. Wilburt C. Davison, dean of Duke University School of Medicine, Dr. Samuel Proger, professor of clinical medicine, Tufts College Medical School, and Mr. Fred J. Kelly, chief, Division of Higher Education, of the U. S. Office of Education.

The Monday afternoon session will be devoted to discussions of current wartime problems. The Offices of the Surgeons General will be represented. In addition, "Medical Manpower for Civilians" and "Wartime Graduate Training" will be presented by Dr. Harvey B. Stone, vice chairman, Directing Board, Procurement and Assignment Service, and Comdr. Edward L. Artz, M.D., chairman, Wartime Graduate Medical Meetings. On Tuesday, February 15, there will be programs by the Federation of State Medical Boards. The Council on Industrial

Health will hold its Annual Congress on Industrial Health on Tuesday and Wednesday, February 15 and 16.

All meetings will be held in the Palmer House in Chicago. It is urged that all who have not made reservations do so at once.

Complete details of all programs will be published shortly in THE JOURNAL.

THE CHICAGO SESSION

Applications for Hotel Reservations

A list of Chicago hotels, together with the rates for rooms, may be found on advertising page 56 of this issue of THE JOURNAL. With the list may be found an application form that may be used to secure reservations through the Subcommittee on Hotels of the Local Committee on Arrangements. This application form may be clipped and, when it is properly filled in, should be sent at once to Dr. Fred H. Muller, Chairman of the Subcommittee on Hotels, Chicago Association of Commerce, 1 North La Salle Street (23d Floor), Chicago.

Those who expect to attend the annual session of the American Medical Association should send in their applications at the earliest possible time. Applicants for reservations are especially requested to include a second and a third choice in order that good accommodations may be secured if the desired reservation cannot be had at the hotel of preference. It will greatly expedite matters if requests for reservations are addressed directly to Dr. Muller.

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS OF CONSTITUENT STATE MEDICAL ASSOCIATIONS

SECOND SESSION, FRIDAY AFTERNOON

(Concluded from page 112)

The Council on Medical Service and Public Relations of the American Medical Association

DR. LOUIS H. BAUER, Hempstead, N. Y.: If there has ever been a council appointed in the American Medical Association that has aroused interest, it is the Council on Medical Service and Public Relations.

The Council has definite functions which were set up in amendments to the By-Laws. The Council has been under considerable handicap in that it cannot function until its policies are adopted and its organization and functioning approved and until it has a permanent secretary. Dr. G. Lombard Kelly, dean of the Medical School of the University of Virginia, is here and will take over on January 1.

The policies of the Council have been sent to the secretaries of all state societies, to editors of all state journals and to the chairmen of all legislative committees. Our function is not just to oppose hostile legislation. I believe that may be an important function but perhaps an incidental one. We hear criticisms of the American Medical Association and of the American system of medical care to the effect that it does not cover all the people. We have been deluged by statistics on the number of people without adequate medical care, most of these statistics coming from sources which made the statistics fit their arguments. Nevertheless I think we are agreed that there are certain people who perhaps do not have adequate medical care. It makes no difference whether there are 1 million or 30 million people without proper medical care, the aim should be that if there is 1 person without proper care we should endeavor to see that that person gets that care.

The ordinary statement we hear made about the Wagner-Murray-Dingell bill is "You oppose this; what have you to

offer in place of it?" They would like to have us offer amendments to that bill. This I think would be the wrong thing to do. Those amendments would be introduced, but by the time they got through Congress I am afraid we would not recognize our child, and it would then be our bill. We must not be stampeded into offering any set plan. We do have to take time and pains to point out what American medicine has to offer in place of compulsory sickness insurance. To my mind the most important function of the Council is to study and assess all the various systems of medical care which have been proposed and make an effort to evolve something or several things, possibly, that will meet the situation over the country.

I think every member of the Council is much impressed—in fact, I might say almost overwhelmed—with the magnitude of the task which is before us. Every one is taking it in the most conscientious manner. How much we shall be able to accomplish I do not know. If you are expecting us to become ultra-conservative you will be disappointed. If, on the other hand, you expect us to become ultraradical you are going to be disappointed. If you expect us to work miracles overnight you are going to be disappointed, because none of us are miracle workers.

We have approved group hospital insurance. It is estimated that from 12 to 15 million people in the United States have group hospital insurance. Well, that is only about 10 per cent of the population of the United States. I think that is something that must be furthered, and it is up to the doctors to help further it.

We have approved the principle of voluntary medical expense insurance. There are a number of plans which are in vogue, in operation over the country. I believe I am safe in saying that not one of them has been a 100 per cent success. That does not mean that there is anything wrong with the principle. It may mean that we have not yet worked out the proper formula, and that will take time and study. I understand it took forty years to establish life insurance. Nobody would doubt the success of life insurance at present. I do not mean to imply that it is going to take us forty years to work out

voluntary expense insurance, but it is going to take more than two or three years to do it. I think the medical profession itself, the individual doctor, has been a little laggard in his efforts to further plans which have been adopted in his own state. It would be a mistake to think that we can take one plan and make it fit the whole United States. One of the arguments which we have had against compulsory health insurance as well as many other arguments is that we believe no one system is suited to every section and every class of people in the United States; if that is true of the compulsory, it certainly is equally true of the voluntary.

There is a good deal of interest now in industrial medicine. There have been various industrial plans evolved. One of those that we have heard most about is the Kaiser plan. Mr. Kaiser thinks that his plan is the panacea. I asked him how he thought it was going to work in a rural area with perhaps a population of five persons per square mile, and he thinks it will work, but he did not say how. He said he was going to take it into the rural districts of California and find out. I say let him do it and see what he does find out. There were some good points about Mr. Kaiser's plan and others that are not so good. I question in my own mind if it is the answer. In fact, I am sure it is not the answer. It may be the answer for certain mushroom industrial populations such as it is in effect for at the present time.

We have heard about diagnostic centers; we have heard about state aid in reducing the cost of more expensive therapeutic agents. All those things are matters for study and perhaps solution. When we get through I believe we shall find we shall not have one answer but several answers. What will work in California will not necessarily work in Massachusetts, and what will work in an industrial area will not necessarily work in an agricultural area. We may have to have several plans before we get through. The only way you can work out a satisfactory plan for any area is by experiment and gradual evolution and modification. The Council is not in favor of anything revolutionary. We do hope by the time our job is done, if it ever is, and if not some one else will take it over, that we can offer a system of medical care that is in accord with the American tradition of free enterprise and the American standards of excellent medical care.

The Council has been organized with a chairman, a vice chairman and a full time secretary. An executive committee of three has been created, which includes the chairman, the Council member of the Board of Trustees and a third member elected. The executive committee will have such duties as may be delegated to it by the Council itself.

In order to get all the information necessary to study various plans of medical care, and to know what is being proposed in the legislative world, the Council must have certain sources of information. The American Medical Association has had sources of information, and those are being amplified and extended. We shall have perhaps more opportunity in the future to know just what is going on. But you state secretaries have also got to serve as sources of information, particularly with reference to the various plans of medical care which are going on in your vicinity. We feel we have to maintain close contact with the state societies and the county societies. We have asked each state secretary to have the proper body in his organization designate an already existing committee, or in its judgment appoint a new committee, to act in collaboration with the Council in carrying out our activities. Those letters went to every state society; at the present time we have had replies from nineteen. Some of the replies merely acknowledged receipt; some designated committees; some went so far as to give their whole county setup as to how they wanted us to function with the county. One state has resurrected a former system which they had in 1934-1935 and has gone into it with a great deal of detail. That is the state of Indiana. They have here today an outline of their plan. The Council has not yet seen it. We are going to study it tomorrow at our meeting.

The By-Laws stated that we should establish collaboration with the Bureau of Medical Economics, the Department of Public Relations and the Bureau of Legal Medicine and Legislation. Those contacts have been made. Briefly, the Bureau of Medical Economics has been asked and has expressed its

willingness to do the research on many of the economic problems necessary for Council study. That bureau is well equipped to carry on that research. You state secretaries have a job to do in seeing that the Bureau of Medical Economics or our Council is kept informed of what the status is of the medical care situation in your locality. We expect to establish joint bulletins with the Bureau of Legal Medicine and Legislation on legislative matters and to effect a wider distribution and, if possible, a little more frequent distribution of those bulletins, as well as bulletins of our own. We want these to reach the profession. We have also established relations with the Department of Public Relations. We are going to utilize the sources of information which that department has. Our whole effort is to avoid overlapping of the functions of these various bureaus. There is the most cordial relationship among all the bureaus here in the headquarters office, they are out not to obstruct one another but to help one another. We can make use of the various sources of information which may be established in various places. The secretary is being authorized to travel wherever necessary, in the judgment of the Council, where he can make contact with the various agencies and transmit the information from the Council and bring back information to us.

One of our important functions is to disseminate information that we have accumulated. That can be done, of course, through *THE JOURNAL*, *Hygeia*, the various state journals and those counties that have publications; and of course there will be a certain amount of material which should reach the public. That, I believe, to a great extent will be more effective when it is issued locally. Things which are issued nationally get through the various large press organizations but are apt to be pretty much abbreviated by the time they reach the local papers. A great deal can be done by the local units in furthering publicity of any of our aims.

I believe we have to realize that we must sell ourselves to the public as well as to the medical profession. The public is not aware altogether of what the American Medical Association stands for. As Dr. Kretschmer brought out, there is some vocal disapproval of the American Medical Association, but by large the Association stands pretty well. I believe we should endeavor to combat propaganda which is aimed at us and which is distinctly unfair and based on false premises. That can be done only by contacts with the individual physicians, with the individual organizations in their localities and their individual patients. That requires time on the part of the doctor. It is our feeling that this council is merely the center from which information will go out and to which it will return, but that same sort of thing must be done in each state and each county. Each county society must be a bureau of information for the public as to what our principles are and what we actually stand for.

DISCUSSION

DR. R. L. SENSENICH, South Bend, Ind.: The purpose of this method of public relations is "by means of frank discussion, to establish with the groups contacted that friendly relationship which exists between patient and physician in the home, to the end that the best measures may be instituted for the solution of their mutual problems. It is desirable that these friendly contacts be maintained and be not limited to the consideration of possible impending harmful legislation. In times of continuing social adjustments the value of the understanding and support of a friendly lay public cannot be overestimated." That was the background of the Indiana plan. First, it was built on the premise that an effective physician to public contact was lacking. Second, the physician was not sufficiently informed. I regret to say that I think that is true even today. Third, some appraisal was needed covering the whole problem, both from the standpoint of the physician and from the standpoint of the public: What the public really lacked in medical care, if anything, or what it thought it lacked and what it should have and how it could be attained acceptably to both. Fourth, this method would provide a sort of perpetual inventory through which we would know the attitude of those who would influence legislation, not alone individuals but groups, the employees and the employer groups, and all the other social groups. Fifth, it would include the medical societies and their public relations. Sixth, with the better informed profession

more individuals will be in position to lead, to mold public opinion and help in the direction of the development of such plans as are necessary to meet the needs. Seventh, the council now replaces the legislative committee in the plan or organization. Eighth, the project to a great extent should be that of state and county societies. Ninth, the basic policies must be fixed by the House of Delegates of the American Medical Association. Tenth, plans of action should be formed at the national level at this time by this newly created council on which has been placed so much responsibility and from which we expect so much. Eleventh, each state and each county should be permitted the widest latitude in the matter of its organization, provided it proves that in the particular area it is the best method of approach to the public relations problem involved. Twelfth, the plan is workable.

DR. CARL H. McCASKEY, Indianapolis, President Indiana State Medical Association: Dr. Sensenich has given you the history, the background, the reasons for the adoption of the Indiana plan by organizations. What are some of our contacts in Indiana? First, we have this contact with the Indiana Chamber of Commerce. We have close contact in Indiana, through this working plan, with the Hospital Association. We have close contact with the insurance organizations of the state, the Pharmaceutical Association and certain labor groups which are particularly opposed to the plan set out in the Wagner bill. We have the support of the Manufacturers' Association in Indiana, through working out with them of this plan which has been presented to you. This plan gets down to so-called grass roots of the organization of medicine. It gets down to the man who has to buy medical service or who has to be given medical service. You have a chance to educate the public through this plan on the things that American medicine is doing for it.

DR. G. LOMBARD KELLY, Augusta, Ga.: I agree with Dr. Bauer in regard to the stupendous task this committee has. I feel with awe the undertaking ahead. Only my intense interest in organized medicine, selling the medical profession to the public, persuades me to take on the work of secretary of this committee. I would also like to agree with Dr. Bauer on the need of the cooperation from the secretaries and editors, and the medical profession as a whole.

DR. W. H. TOULSON, Baltimore: I would like to ask the committee what attitude it would take toward the National Physicians Committee.

DR. BAUER: The attitude of the committee on that question really came from the House of Delegates. In the policies of the Council which were sent out a statement was placed in them relative to it: "There is no official affiliation between the American Medical Association and the National Physicians Committee. However, since it is the purpose of the National Physicians Committee to enlighten the public concerning contributions which American medicine has made and is making in behalf of the individual and the nation as a whole, it is the opinion of the Council and the medical profession that we will support the activities of the National Physicians Committee and other organizations of like aim." We welcome any help any one can give us. We had statements of policy relative to the Wagner bill from other organizations beside the National Physicians Committee and we welcome their support also. The American Bar Association has come out against it. There are many prominent newspapers in the country which have come out against it. Various church organizations have come out against it. The monthly or weekly organs of the Methodist Church and of the Catholic Church have both come out strongly against it.

DR. VINCENT T. WILLIAMS, Kansas City, Mo.: Is it not true that if you want to reach the grass roots it might be as a matter of constructive suggestion that these folks who work on county bulletins be apprised of what your committee or council is doing, as rapidly as possible?

DR. BAUER: That is true.

DR. WILLIAMS: I believe you made the statement that your council had come out formally endorsing certain prepared plans?

DR. BAUER: No, I did not say that. I said that the council had under consideration these various things and that I thought it would be a mistake for the Council to endorse any plan at the present time, because I don't know of any plan which is 100 per cent satisfactory; but I do think we should study all plans and see if we could evolve something that would be satisfactory. We haven't endorsed any of them as yet.

DR. WILLIAMS: Was it the principle of prepared plans that your Council did endorse?

DR. BAUER: We have not endorsed anything other than what the American Medical Association has already endorsed, namely, the principle of voluntary insurance.

DR. WILLIAMS: May I ask, then, as a constructive suggestion, that the county societies (I believe there are only about one hundred that have bulletins) be put on your mailing list to get some of this information.

DR. BAUER: We have asked all state secretaries to send us the list of any county societies in their state which they wish placed on our mailing list direct and have asked them either to forward the material which we send out to every county society or, if they prefer, to send us the names and addresses of the county societies so that we can make direct contact with them. Some states have already sent in that information; some of them have asked us to make direct contact with the societies; others have asked us to send material so they can send it out. We feel that is a function of the state society to decide how it wants to do it. We are willing to put anybody on the mailing list who is interested. We just want to be sure you are interested. There is no use sending material to a county society if it does not have any active committee. We are only too delighted to place any county society which is interested on our mailing list. That is why we are anxious to get back the replies from these other thirty states, so we can get our mailing list up to date and so everything we send out will reach everybody who is interested in it. It will cover not only state secretaries and other such county secretaries as request it but the legislative committees and the editors of all the state journals, and anyone else who wants to be put on that list can be included.

DR. GEORGE H. KRESS, San Francisco: On October 10 the council of the California Medical Association voted \$5,000 to make a spot survey of California to find out what, if anything, is wrong with medicine. If the survey justifies, the council contemplates the expenditure of some \$30,000 more to see what can be done to rectify conditions.

Reference was made to a lobby in Washington. The council of the California Medical Association saw fit to approve the plan of sending the secretary of the California Public Health League to Washington, where he is now, to make more intimate contacts with the congressmen from California so that the California Medical Association would be in a better position to advocate those legitimate propositions concerning the public health and medicine that may be deemed worthy of support.

Reference was made to the Kaiser plan. You may be interested somewhat in having a brief reference thereto, because many of you are not on the ground and are not familiar with the situation. Some of you may have read Paul deKruif's book "Kaiser Wakes the Doctors." In the Kaiser Foundation plan they did deal with almost 100,000 men. Let's take the figure of 100,000, because figures are so massive when you transpose them into money values that you can make your own deductions and still see why the Kaiser plan in a limited geographic area in the county of Alameda can do the things that presumably have been accomplished. First, the 100,000 men are comparatively good risks, and at \$2 a month per employee, or \$200,000 a month, you have an income of \$2,400,000 a year. Industrial injuries are cared for and paid for from the State Industrial Fund of California to the extent of 40 per cent; add another \$1,000,000. You have then for the Permanente Foundation approximately \$2,000,000 to \$3,000,000. No wonder that Mr. Kaiser, under those conditions, with practically no acquisition expense in the securing of his risks, and with no medical care to families, can set aside \$25,000 to \$50,000 a month in

paying off the expenses incident to the erection of his hospital in the city of Oakland. But when Mr. Kaiser uses that as a basis of analogy and proceeds to say to the people of the United States that on 7 cents a day he can give treatment to families as well as to employees (instead of dealing with one employer with deductions at the source and with practically no acquisition expense, and with perhaps whatever acquisition expense is involved coming from federal funds, and all that done in limited areas instead of over a massive state such as California and dealing with many employers with all kinds of employees); I say that when he tells the people of the United States and the medical profession that he has found the solution to the problem of adequate medical care he is guilty of erroneous thinking and conclusions, as must be evident to any thinking person when the situation is analyzed. Those of you who are interested should read the October issue of *California and Western Medicine*, in which there is a tear-down of Paul deKruif's book and in which the inside story is told. You can get the real facts from the book review that is there given, with the excerpts and comments.

DR. BAUER: That is exactly the type of information which the Council wants. Kaiser thinks his plan is a panacea, and we question it very much. It may be an answer in certain situations, but does it answer for the whole United States? The fact that the Kaiser plan has had such national prominence makes it necessary that we study it and give information to show why it will not work; we can't just ignore it. The people in California are peculiarly well situated to give us information, and we are going to expect California to give us that information. That is why I say this is going to be a two way affair. You people who are on the ground and who are observing the functions of these plans can give us information which we must have before we can stamp any plan as being good, bad or indifferent.

DR. OLIN WEST, Chicago: There is the most encouraging thing I have seen in fifteen years [referring to the Indiana Society's brochure]. I have not had time to read it or study it. I don't know whether I would agree with everything in it or not, but those of you who have a copy of it will see that it is published by the Indiana State Chamber of Commerce. It is well presented. I presume it is being distributed in considerable numbers. This is the first time that I have seen any definite evidence that they have really become interested and are willing to try to help do the job that has got to be done. We made a long, persistent and intensive effort to get organizations of this kind interested in the fact that the first introductory steps toward efforts to establish socialization of medicine, regimentation of the medical profession and political control of medicine in this country indicated that the next step would be to socialize something else, and the next step something else, and to bring about a complete system of federally controlled life in the United States. I am encouraged that we are receiving inquiries here from commercial organizations, from industrial organizations, from civic clubs, from various groups, not only of physicians but of laymen and lay women who are working to see that this legislation, which has been introduced, is defeated. There is a growing interest on the part of men who are interested primarily in business. They are beginning to realize that in every instance in which socialization has been effected in a nation the first step has been to take up some proposal that makes a strong, popular and an even more strong purely sentimental appeal. It has been true in practically every country that now has a system of compulsory sickness insurance. They always start with the mother and the baby, or with the poor, downtrodden and underprivileged. We made a very earnest effort to interest financial groups, commercial groups, organized groups of industrialists and others. They said that was not their function. The work the medical profession has been doing in trying to stave off socialization not only of medicine but complete socialization is now beginning to seep into the minds of business men and of others who prefer to lead their own lives under democratic principles rather than to be politically dominated in every movement they make, from the cradle to the grave.

FRIDAY, NOVEMBER 20—MORNING

DR. JOHN S. BOUSLOG, Denver, Presiding

A paper on "Medical Legislation in Congress," was presented by Mr. J. W. Holloway Jr., Director of the Bureau of Legal Medicine and Legislation of the American Medical Association. He analyzed legislation pending at the time.

DISCUSSION

DR. STANLEY B. WELD, Hartford, Conn.: Has the Barden-LaFollette bill any relationship to the present emergency or is it a permanent affair?

MR. HOLLOWAY: It is permanent.

DR. WELD: Is there being any difficulty found in financing the relocation of physicians, such as you implied there might be, in your remarks?

MR. HOLLOWAY: I did not imply there was. I simply said that this proposal had been made to finance them.

THE CHAIRMAN: There is a lot of legislation in the Congress that we know nothing about.

DR. WALLER S. LEATHERS, Nashville, Tenn.: May I make this statement, Mr. Chairman: I think Mr. Holloway has presented a clear and helpful discussion about this legislation. Any one who has any idea of legislation realizes that the way in which he has done it shows that he is intimately associated with it and has undoubtedly followed the program remarkably well.

THE CHAIRMAN: I agree with you heartily.

The Federal Plan for Providing Obstetric and Pediatric Care for Wives and Infants of Service Men

DR. L. FERNALD FOSTER, Bay City, Mich.: At this time any presentation relative to the U. S. Children's Bureau plan of providing obstetric and pediatric care for the wives and infants of service men can be only one of reporting observations and views as gathered from various physicians throughout the country. Already each state association probably has taken some action relative to this subject, either having accepted the plan as presented, rejected it in toto or accepted it with modifications. A discussion of the plan a year ago, when some uniformity of action might have been developed, would probably have been more apropos. The history and background of the Children's Bureau plan, including the action of the 1943 American Medical Association House of Delegates, is well known and needs no reiteration today. The war-emergency offered a good opportunity for the proponents of the present program to utilize the great interest appeal of maternal and child health for the families of service men. Is this project, embracing a small segment of medical practice, being utilized as a trial balloon for complete federalization of medical practice? Are the proponents of a plan of complete federalized medical care watching the attitude of the medical profession toward this plan in order to determine what their activities shall be, either to make bolder strides toward their totalitarian objective or to retreat from their grandiose scheme?

Many physicians question the sincerity of purpose in this program. In the first place they are suspicious of this measure, which was enacted not as an independent legislative proposal but as an amendment slipped into an important appropriation act. They further suspect sharp practice in the wholesale premature publicizing of the program to the thousands of service men in camps before the matter was even presented to the necessary purveyors of the services, the doctors. Physicians resent the modern method of "legislation by edict" as exemplified in the ruling by the Children's Bureau that payments cannot be made to the service men's wives but shall be made direct to physicians. Many physicians say that the published reports of approval by forty-five states are misleading in that the plan approved was in many instances that of the state health department and not of the medical profession of the state. Many state medical societies have not given approval, and after all it is the private practitioner who must do the work. These physicians feel that no program, no matter how worthy, can be successful if founded on bad faith and lack of mutual trust.

The main objection to the program is expressed in the American Medical Association resolution: payment direct to doctors of medicine. Every one, including the dependents themselves, would favor a program based on allotments to service men's dependents. There appears to be nothing in the law (the brief amendment to the appropriation act) that specifically prohibits payments to service men's families. The present refusal of the Children's Bureau to try such an arrangement is based on a mere legal opinion. In one Midwestern state the program had been accepted and was working well because opportunity was given the doctors to make supplementary arrangements. When a representative of the Children's Bureau heard of these arrangements, the plan was changed immediately and the possibility of supplementary arrangements was deleted. That state has since given its disapproval to the plan.

Further serious objection lies in the fact that the plan does not take into consideration obstetric complications, emergencies and compensation commensurate with care demanding special technical skill. Such lack of consideration would tend to lower the quality of care—which is one of the most serious objections to all schemes of federalized medicine. Considerable objection has also been made to the very meager provisions for pediatric services. The actual need for such a broad program as the present project promises to be is questionable. However, the widespread publicity given the plan has definitely stimulated a big demand. The bait of "something for nothing" is always alluring to the unthinking populace. It is incomprehensible to the average American that his wife and children's free obstetric and pediatric care may lead to complete regimentation of medicine, which in itself may be the entering wedge for the general socialization of the country. Experience has shown in many cases that where the doctor has had the time to explain the implications of this scheme to his patients they prefer to remain private patients instead of becoming charges of the federal government.

Doctors in states which have refused to approve the plan in its present form are concerned over the position of those state medical associations which have endorsed officially the federal program of obstetric and pediatric care. They have established a precedent which is not consistent with their general opposition to complete state medicine. This action by state associations is being utilized to good advantage by representatives of the Children's Bureau in their attempts to influence other states to adopt the program. It has helped to make the stand of some state associations extremely difficult and almost hopeless.

In my own state the House of Delegates took the following action in September 1943:

(a) "Because this plan is a form of state medicine the Michigan State Medical Society refuses to cooperate in any of the provisions of the plan in its present form.

(b) "That until satisfactory adjustments in the program can be made the members of the Michigan State Medical Society are requested to give professional care gratis in order that the wives and children of servicemen may obtain hospital care."

It has been recommended to the U. S. Children's Bureau that payments be made to doctors of medicine through Michigan Medical Service, our voluntary group medical care plan. A poll of our membership has been taken and it indicates that such an arrangement is approved by a great plurality. A special committee is handling negotiations with the Children's Bureau and Michigan Medical Service at the present time.

The feeling of the medical men in Michigan, where Michigan Medical Service covers the state and where, through Michigan Hospital Service, it invokes the services of 98 per cent of our hospitals, and where Michigan Medical Service is the plan of the profession itself, the profession would be willing to have this service purchased; since we are told that the funds must be used to purchase the services, the profession seems willing to have it purchased through their own organization if that will solve the problem, which it probably would do in Michigan if such a plan were acceptable by the Children's Bureau.

Pending the outcome of these negotiations and being cognizant of the many local problems confronting the profession throughout the state, the executive committee of our council has registered the following opinion:

1. An unalterable disapproval of the plan in its present form.

2. That the members individually might properly—as they deem fit—(a) sign the blanks to provide hospital service, giving the professional care gratis, (b) sign the blanks and accept the government fee or (c) decline to participate in the program. In any event the Children's Bureau plan has been so developed, timed and publicized and so administered that the medical profession in almost any position it takes has been placed definitely on the defensive. It must get on the offensive.

In conclusion, the whole subject might be summarized as follows:

1. Every one is desirous of having quality medical service accorded the dependents of our fighting men.

2. The program of the Children's Bureau is definitely one of federalized or state medicine with direct subsidization of physicians.

3. It does not insure quality service.

4. Federal health and medical projects are seldom discontinued after an emergency—this program is probably no exception.

5. The plan gives no assurance of a maintenance of reasonable fees (even if the present fees were considered reasonable).

6. The program is not limited to doctors of medicine.

7. The program could be used as a precedent to extend federal medical care to all branches of medicine and surgery.

8. Complete refusal to cooperate in the plan, even with an offer to render service gratis, might well evoke a criticism of the medical profession.

9. Official acceptance of the plan is a definite approval of federalized medicine.

10. Where participation in the plan seems necessary, might it not be better to make such a participation on an individual basis—not on a basis of official approval by state associations?

DISCUSSION

DR. EDWIN F. DAILY, Washington, D. C.: Dr. Foster states that he dislikes the Children's Bureau "edict" that payments cannot be made to the wives of service men. That is not an edict of the Children's Bureau. The law, as it was passed, was given to the solicitor of the Department of Labor, and we asked his interpretation as to its intent in this respect: At that time we were told that the wording of the act was "to provide medical, nursing and hospital care" and that it was not the intent of Congress that it be a benefit payment but that the funds were to be used actually to purchase medical and hospital care. The solicitor of the U. S. Department of Labor in a formal opinion dated Dec. 12, 1943 advised as follows: "It is my opinion that the chief of the Children's Bureau has no authority to approve state plans which provide cash allowances to the wives of enlisted men in lieu of the existing method of making payment, through the state health agencies, directly to cooperating practitioners and hospitals."

Further, when additional appropriations were being considered by Congress within the past two or three months an amendment was proposed by a Congressman specifically to provide for a benefit payment instead of purchasing care directly from the doctors and the hospitals. This amendment was defeated, as mentioned by Mr. Holloway. We are now acting in accordance with the law, and I think the position of the Children's Bureau is quite clear.

One minor point in Dr. Foster's statement: He speaks of the director of maternal and child health in the state department of health as being the representative of the Children's Bureau. The directors of maternal and child health in a state are employees of the state health department and are in no way responsible to the Children's Bureau. We have no employees of the Children's Bureau who are working in the states. We have a small staff of regional consultants who act in an advisory capacity.

Dr. Foster made a statement about a physician from Iowa, a member of our advisory committee, who made a statement before the Michigan State Medical Society concerning supplementary payments to the physicians. I had a letter from Dr. Plass in Iowa regretting that he had been misinformed when he went to Michigan, and when he returned to Iowa he found the statement he made was incorrect.

The statement was made here that the plan does not take into consideration any emergencies or any need for any other conditions that may arise during pregnancy. All state plans do provide for medical consultation, and general practitioners can call in a consultant in any specialty whatsoever when one is needed. If he needs a surgeon for an appendectomy, if a general practitioner needs an obstetrician to come in and advise and assist him, all of the plans make provision for any service that the individual needs. If the patient needs hospital care for any complication during pregnancy, provision is made for that. The plan provides for any type of service the individual needs, of course, that is, when that service is or can be made available within the community.

A few more words about the benefit payment: There has been an enormous amount of discussion pro and con as to whether or not it should be a benefit payment to the families or whether the plan should be used to purchase care directly from the doctors and the hospitals.

I think it should be understood that a benefit payment would be unquestionably on a uniform basis, a certain amount—\$50, \$75 or \$100—whatever might be established by Congress as a uniform benefit. One Congressman estimated that the cost of the program would be at least double what it is at the present time since every enlisted man's wife who is pregnant or who has a child under 1 year of age would undoubtedly request and receive the benefit. At present we estimate that only approximately half of the enlisted men's wives who might request this care are applying for such care under the program.

A benefit plan would not take into consideration the great variation in need of individual maternity patients for care. All the states have found that the cost of care between individual cases varies tremendously. Here is Mrs. Jones, who will require perhaps two or three weeks of hospital care in the middle of her pregnancy, for some complication. Perhaps there will be need for prolonged hospital care at the time of childbirth. Those are provided for in the plan. Perhaps consultation is needed, which may run the cost up quite a bit for a certain case. Or maybe the wife has a prematurely born infant who has to stay in the hospital for six or seven weeks. Those variations can be taken into consideration under the present plan and are being taken into consideration. On a benefit payment basis that would not be true. Under a benefit payment plan there could be no assurance that the funds paid to the individual would be used for medical and hospital care, there would be no assurance that the doctors would be paid or that the hospitals would be paid.

All the medical service plans that I know of in this country which are sponsored by the state medical societies provide for payments directly to the doctor, and under the hospital service plans they provide for payments to the hospital. I believe in the history of that type of medical or hospital service plan in this country the principle of payment of a benefit has long been discarded as not practical. Perhaps some of those present here who are familiar with those plans will verify that statement or correct it. In studying some of these plans recently I find that the medical service plans of the state medical societies usually set an annual income of \$2,000, \$2,400 or \$3,000, or something like that for the low income group who are covered by the plans. They establish a fixed payment to physicians which ranges between \$40 and \$60 for maternity care; that constitutes the sole payment to doctors for the service they rendered under the plan, which I believe is somewhat comparable to the provision that has been made under the E. M. I. C. program.

DR. W. W. BAUER, Chicago: I have been a member of the Advisory Committee to the United States Children's Bureau since the committee was established. I should like to make it clear just what the status is of that advisory committee. As its name indicates, it is advisory and nothing more. The medical profession, that is, the American Medical Association, was not asked to appoint a representative. There was correspondence requesting the Association to suggest a member for the Advisory Committee, but not as an official representative of the Association. The Secretary of Labor invited me to be a member. I submitted that invitation to the Board of Trustees, and the Board of Trustees approved acceptance of it. That invitation has twice been renewed, each time for a three year period,

and each time has been accepted in the same manner. This committee has no authority whatsoever. The decision as to the policies of the Children's Bureau rests with the bureau and can be influenced by the committee only as far as the Children's Bureau finds the advice of the committee acceptable. That fact has given rise to an increasing feeling among the members of the committee that there is something inadequate in the relationship. At the last meeting of the U. S. Children's Bureau Advisory Committee, which was held in Washington on October 21, that feeling was definitely expressed by members of the committee in a statement in the more or less informal discussion, to the effect that the representatives on the committee did not truly represent the practicing physician.

I quite frankly admitted that as one who has not practiced medicine for twenty years I was perhaps somewhat remote from the problems of the practicing physician. Other medical representatives on the committee, including full time professors in medical schools and men and women engaged in public health work, freely acknowledged the same. Out of that discussion there came a recommendation from the Advisory Committee to the Children's Bureau that additional representatives be invited and that these representatives be men or women actually in the practice of medicine and acquainted with its problems. This has since been done (THE JOURNAL, January 1, p. 46).

I presented at this advisory committee meeting the resolution of the House of Delegates calling for direct payments to the recipients of medical care and permitting them to make their own arrangements. Many of the members of the committee, particularly those engaged in social work, disagreed with me and presented their arguments to the contrary much as Dr. Daily has presented them, to the effect that this method has been found unsatisfactory, that there is no assurance that the money will be used for the purposes intended, and so on.

The Children's Bureau, as Dr. Daily has stated here, took the position that it is obligated by implication, at least, by the defeat of that amendment to which Mr. Holloway referred, to furnish medical care and to pay the doctor direct, and not to follow the recommendations of the American Medical Association House of Delegates. There was no point in any further debate because we had stated our case; to all intents and purposes it had been rejected, and it stands rejected today.

The other principal thing that came out of that advisory committee meeting, which by the way was a very long, intense and spirited meeting, was the discussion of this question as to whether the act intended to provide maternity care for the wives of service men or to provide medical care for the wives of service men when pregnant, those being two distinct things. I gathered the impression that the interpretation of the officials of the Children's Bureau was that these wives, when pregnant, should have what care they needed, obstetric or other. There was some discussion of the question of dental care, and that was excluded because of the insufficiency of funds, although it was stated as a desirable objective.

On this question of whether women were to have all medical care during pregnancy, or maternity care under this plan, plus making their own arrangements for any additional care, there was quite a long discussion, and a compromise recommendation was arrived at. It was not wholly satisfactory to anybody, I believe, but it appeared to be the best on which agreement could be reached at that time. It was recommended to the Children's Bureau that for intercurrent disease occurring during the pregnancy the physician was to receive additional compensation under certain conditions, the principal one being that the disease must be of a duration longer than seven days. That was an administrative problem, some arbitrary line having to be drawn somewhere. As I say, that was a compromise that was not wholly satisfactory to anybody.

Dr. Foster raised the point that this program is a precedent. I don't think there is the slightest doubt of that. I have had many frank conversations and discussions both with Dr. Eliot and Dr. Daily. Dr. Eliot told me at Washington not so long ago, when I said that the doctors would be better satisfied to cooperate in this plan if they could be assured that it is not the opening wedge for broader plans, "I don't think they can have any such assurance." She may have been expressing her own opinion, or she may have been expressing her estimate of the trend of events.

The American Public Health Association had a meeting in New York early in October, this program being the subject of one session, at which time it was presented by a director of child health and maternal health for a Southern state—I think it was North Carolina—and by a county health officer in that state actually administering the plan, and by Dr. Eliot. Dr. Eliot's discussion was purely a technical discussion of administrative problems and difficulties.

The county health officer emphasized several times that this is a plan for the duration. So also did the state maternal and child health director. The first discussor was Dr. James MacIntosh, a Scottish physician, who opened his discussion with this remark: "I have heard it emphasized here twice that this is a program for the duration." Then he smiled and said "Is it, or have you got your foot in the door?" I think he went straight to the heart of the question.

This program began from small beginnings. Under the general social security grants the Children's Bureau and the Washington State Health Department started this program. From there it went to other states and finally was extended, as Mr. Holloway has pointed out, to almost all the states. Now it is established in practically all the states. Where it will go from here I do not believe we have any assurance, but I think it is logical to assume that if the officials of the Children's Bureau are committed to the conviction that this is a program that they ought to further they will carry it as far as they can get authorization and funds to carry it and will extend it from there. That would be the only logical program that we could impute to individuals who are acting sincerely under their convictions.

As a member of the Children's Bureau committee, I have objected on a number of occasions to the officials of the Children's Bureau because they have not laid their plans before the medical profession. This meeting of October 21 is being started by the Children's Bureau. I received the report yesterday. It will be published soon in an issue of *THE JOURNAL*. Previous meetings, in spite of my repeated requests, have not been adequately reported. As an invited member of that committee I cannot publicize those meetings on my own initiative. The announcements should come from the Children's Bureau. I have asked again and again that they be furnished. Some of them have been furnished, but they have not been furnished in nearly the detail or nearly as early as I think would have been advisable for the information of the medical profession.

Let me emphasize again that we on the Advisory Committee are purely advisory. In fact, at the first meeting of the Advisory Committee before which this program was discussed, we were requested to discuss it, to present our individual opinions, but not to offer any resolutions of the committee or any recommendations of the committee as a whole. I don't know why that request was made; I merely state the fact. And of course that was then all that could be done.

One thing which impressed me in the discussions, both in the Advisory Committee, in private conversation with Dr. Dailey and Dr. Eliot, and with physicians and secretaries of medical societies, is the enormous complexity of the administration of even a fractional medical care plan like this. What must then be the complexities and the difficulties that would be involved in a complete federalization of medical care?

DR. LOUIS H. BAUER, Hempstead, N. Y.: Dr. Dailey, I think, heard the resolution which was read here from the American Academy of Pediatrics. I should like to know what the attitude of the Children's Bureau would be toward such a conference between the officials of the Children's Bureau and the various medical organizations mentioned in that resolution and whether they would come into it with an open mind.

DR. DAILEY: I am sorry I can't answer that question. That resolution had not been received in Washington when I left Washington.

DR. M. PIERCE RUCKER, Richmond, Va.: I am beginning to believe that I can't understand the English language. We are told that services cannot be paid for until the application has been signed and approved, and we are led to believe that the service is needed and desired by the service men's wives. I can

interpret acts, and I thought it might be interesting for an obstetrician to tell a few experiences he has had with this plan. In the first place, I would like to preface my remarks by saying that I deem it a privilege to attend the wife of any service man. I have never turned one down, and so far I can furnish free hospitalization, so it will not cost the service man's wife a cent, if it is necessary. I don't like to be put in the position of refusing to attend service men's wives because I don't like the plan or of being called unpatriotic. My experience with the plan is that as soon as you tell a service man's wife "You understand, of course, that you will have to go into a ward?" they put the green slip back in their purse and that's the end of it. She says she doesn't want it, so evidently it isn't meeting the needs that we are led to think it does.

Recently I had an experience to show that you don't really have fair dealing. I had a service man's wife—I didn't know she was a service man's wife until I filled out the birth certificate. I carried her through her pregnancy and attended her in the hospital. They paid me cash, and about six or eight weeks later I got a letter from the father down in Texas enclosing a letter from the state administration, I believe they called it. Anyway, it was from a member of the state board of health. It said "If the doctor will sign the enclosed slip we can get your wife's bill paid." I called up the state board of health and asked whether I should send the man's money back and wait for the money from the government. They said "No; we will write him that we made a mistake." Now this man was a "satisfied customer" until the government interfered.

It doesn't seem, in our neighborhood at least (and there are a lot of camps around us) that they want this attention if you tell them they have to go to a ward, although we will give them the same service in the ward that they would get in a private room. As soon as they hear the word "ward" they fold up the green tickets and put them back in their pocketbooks.

DR. GEORGE H. KRESS, San Francisco: The important things for us to remember are the implications involved in this federal children's program. Ten million men are in military service, and a great majority of them are married. We start then with 20 million citizens, and their fathers and mothers, 40 million more. Also count at least 20 million friends, or a total of 60 to 80 million citizens. And this adult population of the United States is to be educated to what? To accept a mandatory fee table to be in operation from one end of the United States to the other, in which Dr. Edwin Daily representing the Children's Bureau proposed to C. M. A. President Karl Schaupp and me in the office of the State Department of Public Health in San Francisco that the fee should be \$35 to cover antepartum care, confinement care and postpartum care; antepartum care to imply a certain number of visits, Wassermann tests, hemoglobin determinations and urinalyses, with other usual antepartum care; in addition, all necessary confinement care and postpartum service with a visit to mother and child at least six weeks after the birth of the child.

The war may last three, four, five years. In the meantime the people of the United States will be educated to what, as far as this particular line of professional work is concerned? To a fee of \$35, or perhaps in some places \$50, as full and fair compensation. At the conclusion of the war, in the minds of the great majority of citizens, \$35 to \$50 would be a proper fee for all this professional work, covering a period of months, with all its complications as they may arise. It would follow that any physician who would charge more than \$35 or \$50 would be guilty, in the minds of many citizens, of an atrocious, improper act.

In April or May last we held in Portland a meeting of the Pacific States Medical Executives Conference. In our discussion of the maternity-pediatric program the Oregon representatives presented their plan, saying that the money should be paid to the wife and not to the physician. As a member of the reference committee of that conference I sent a copy of our resolution to Dr. John Fitzgibbon, who in turn presented it to the House of Delegates of the American Medical Association, the resolution with minor modifications being adopted by the House in June.

In California we are in full accord with the objective of giving adequate professional care to the wives and infants of

enlisted men. However, the Council of the California Medical Association has voted that it is up to the individual physician to determine what procedure he wishes to observe in this work.

Dr. Edwin Daily, representing the Federal Children's Bureau of Washington, D. C., came to California and gave the C. M. A. Committee on Maternal Care one hour, and then the conference was closed because he had to consult with hospital representatives. In our discussion with Dr. Daily he brought out the fact that the proposed fee was to be \$35 for all of the service already mentioned. I asked Dr. Daily where he had gotten his figures, and he said "From the American Medical Association." I said, "Oh, impossible! They couldn't have given you figures of that kind. I am sure when I go back to my office," I said, "I will be able to find fee schedules passed years ago by component county societies of the California Medical Association in which fees were in excess of \$35 for all of the services you include in your maternity-pediatric program." I did find such schedules, and the fees ranged up to \$500 for complicated obstetric cases. We told Dr. Daily that \$35 for adequate antepartum, confinement and postpartum care was out of the question as far as California was concerned and insisted that the minimum fee should be \$50. Also, as regards California, we would object to the promulgation of the plan unless it was stated in the literature "This program is made possible only through the generous cooperation of the members of the medical profession," and our California State Board of Public Health has been printing such a statement on its literature.

I wrote to Secretary Olin West and asked him concerning the statement by Dr. Daily that in more than three hundred fee bills that had been obtained from the American Medical Association, every such schedule was \$35 or less. Dr. West was unable to find in the files of the Association any record of any such information having been sent to the federal Children's Bureau. All that was found was a record, I think in the American Medical Association Bureau of Medical Economics, of one discharged employee who may have sent such information to Washington. Then I corresponded with Dr. Daily, and from Dr. Daily I learned that the fee bills that he told us were the authoritative fee-bills of the American Medical Association had been received by the bureau as photostatic copies from the files of the United States Public Health Service, the same being all the way from five to seven years old or more. Yet the federal Children's Bureau saw fit to have its representative go across the country with only that kind of authority in back of it, using the same with committees and representatives of constituent state associations and urging them to abide by their program under the exigencies which are now confronting us in a time of war.

On one other point, I think I am correct in my memory, and Dr. Daily can correct me if I am in error. At one point I said "Dr. Daily, suppose the case is a difficult one, say, a difficult forceps case or a cesarean section. What would be the compensation for the specialist obstetrician?" And I think Dr. Daily told us in the beginning that it had to come from the general practitioner's fee. To that we strenuously objected, and Dr. Daily then stated he would be willing that there should be an additional fee up to \$50 for this specialist care, and that he would so recommend, presumably to the federal Children's Bureau.

Of course, we were anything but happy to think that the American Medical Association should not have entered the picture at the very beginning, when the program was got under way by the federal Children's Bureau. That was one reason why an editorial appeared in *California and Western Medicine* for which we were criticized in *THE JOURNAL*. We retract nothing from what we stated in our official journal. We think we were right then. It seems to us that when this program with its extensive implications was being formulated, that somewhere, somehow, our good friends here at 535 North Dearborn Street in Chicago should have got into the picture, should have been back there in conference with the inside executive group of the Children's Bureau and have helped guide it in its course of action. We also felt bad to think that our good friend Morris Fishbein failed to call this program, with its serious implications, to our attention, editorially. We felt he should have given us something over and above what

appeared in little memorandum statements and news items concerning the progress of these Children's Bureau negotiations.

Our Council of the California Medical Association has voted as follows: The Council approved the plan of adequate service and all possible care to the wives of enlisted men and told the members of the California Medical Association that it was up to them individually to do as they deemed best in the premises; calling their attention to the fact that if they signed on the dotted line they would receive \$50, not one penny more, nor could they receive one penny more directly or indirectly for the services rendered. If, however, they did not choose to sign, and if the patient did desire to become a private patient, well and good. However, in order to make available the hospital care to these wives, the patient could still obtain the hospital costs from the California State Board of Public Health if the physicians themselves would refuse to accept any money for their services—in other words, give gratuitous professional service to these patients. That is the program we are following at the present time, and I take it that it will be the program we shall continue to carry on.

It seems to me that all of this discussion of costs involved, or the saving of money to the government, by asking physicians to give services below cost, is beside the major point. We are involved here with great principles and, as has been stated by Dr. Bauer, this maternity-pediatric program may be the foot inside the door on behalf of state medicine; and with all deference to the officials of the Children's Bureau, the statements which have been made today indicate that such a thought is not without justification. Permit me to cite an example to show how governmental departments sometimes work: Yesterday afternoon Mr. Holloway and I drafted a series of telegrams to California representatives in Congress relative to a bill dealing with migrant agricultural workers. Out in California the migratory agricultural situation has been a very big problem. With the aid of the California Medical Association, an excellent medical service has been devised, in full cooperation with the government officials. Comes now another governmental agency, the United States Employment Service, with amendments to Public Law 45, which would take away from migratory workers, who do not secure their jobs through the United States Employment Service, the right of medical service for themselves and their families. That is the way governmental bureaus act.

Now, as to the future of the federal Children's Bureau's maternity-pediatric program: The federal Children's Bureau in the beginning evidently miscalculated the number of patients who would come under this act. Witness the initial appropriation of 1 million, with subsequent deficiency appropriations of 4 million and 18 million dollars. These would indicate that there will be other deficiency appropriations needed to carry on this work.

It is, then, up to the members of the medical profession, through the constituent state associations, so to educate their congressmen that when these deficiency bills are presented we shall have a different tally of votes than when only about 125 members of the House of Representatives voted on how the federal money should be paid. I believe if we are alert to our legislative responsibilities, appreciating the implications that are involved in all of this, even the Children's Bureau will be obliged to sit up and take notice in some of these congressional matters. Congress makes the grants in aid, and the monies are then distributed through the agency of the Children's Bureau to the proper constituted authorities in the various commonwealths. In most cases these are the state boards of public health. The state-boards of public health are then called on to administer the act, but if the state boards of public health do not conform to the program outlined by the Children's Bureau they are held up in the usual governmental bureaucratic manner.

I shall be glad to have Dr. Daily discuss some of these other phases rather than the costs. With all the billions and billions of dollars that are being spent for a host of things today, I am but little concerned with whether the Children's Bureau save 5 million or 10 million dollars in this work, all at the expense of the medical profession. But I am terrifically concerned with what will be the end result to medical practice and to the quality and type of medical care and medical service we all believe in, if some of these bureaucratic endeavors are carried too far.

DR. WALTER L. BIERRING, Des Moines, Iowa: As a state health commissioner, I have been in a position to observe some of the administrative difficulties attending the Emergency Maternity and Infant Care program. It is difficult to understand the attitude of the Children's Bureau in determining the administrative plan without previous conference with the professional agencies that are responsible for rendering the service to the wives of enlisted men. This apparent lack of confidence in the practicing physician is evident in the difference in the fees allotted for maternity service ranging from \$35 in some states to \$50 in others. The fee allotted to Iowa was \$35, while in a later arrangement the fee was fixed at \$40 in the adjoining states of Wisconsin and Minnesota and \$50 in Nebraska. There is nothing in the Congressional Appropriation Act that restricts the attending obstetrician from accepting additional fees for the service rendered, but the Children's Bureau requires that he so obligate himself in signing the application. It is claimed that the American doctor cannot be trusted. In the words of the Children's Bureau, "if this were permitted there would be no purpose in the plan." What strange logic. The attending obstetrician may be certified by the American Board of Obstetrics and Gynecology, but if a complication should arise during the pregnancy he is required to call in a consultant whether he is certified or not. While medical fees are fixed, hospitals are allowed \$5.50 a day up to a limit of \$500 for one year and later on a per diem cost basis, which in some instances has been \$7 a day and over. Frequent appeals have been made to have these inequalities corrected without result. There is but one tribunal, and that is always right. Without the fullest cooperation of the practicing physician, no federal plan of medical service can succeed or fulfil the purpose for which it has been established.

DR. MORRIS FISHBEN, Chicago: I would like to refer briefly the attitude of *THE JOURNAL* toward this situation and to make some remarks in extenuation in relation to the various editorial comments that have appeared on the subject in various publications. I would like to emphasize particularly some of the statements made by Dr. Bauer in relation to the technic of operation of those in charge of the Children's Bureau. Obviously the technic they employ to control as far as possible in a completely autocratic manner the methods of their operation is a well designed and worked out technic, designed to achieve the objectives that they achieve. The advisory committees that they select (bear in mind that they select their own advisory committee) are carefully chosen to produce a preponderance of sentiment leaning toward the objectives that they desire to reach. It is not a representative committee of the thought of the medical profession of the United States. The presence of Dr. Bauer on that committee, chosen as an individual, does not in any way represent the official actions of the American Medical Association or of any similar group in the United States. All of you know that it would be quite possible for any one to pick from any group seven or eight who would be definitely opposed to the majority of sentiment. The advisory committee chosen by the Children's Bureau does not represent American medicine. I would emphasize the analogy to the proposed advisory committee under the Wagner-Murray-Dingell bill. Under that bill there is an endeavor to set up such a pattern. The Surgeon General of the United States Public Health Service under that bill is authorized to set up an advisory committee which he himself appoints, and then he may take the advice or not, as he pleases. There again is a pattern for autocracy by bureaucracy, and that is something to be condemned with the utmost condemnation that medicine can provide.

A second point on which I would lay particular stress is the observation of secrecy in action until opposition becomes too late. Dr. Bauer as a member of that advisory committee has not the right or privilege, when he returns here to Chicago from a meeting, to tell publicly what went on. He must reserve such statements until they are officially released by the agency which he advises. The timing seems invariably such that it is all over before we can print what happened. That seems to be the pattern of action by the Children's Bureau. As to whether or not any one can accomplish anything in this problem remains to be seen. For many years there has been a deter-

mined effort throughout the United States to get coordination of health activities under the federal government. There was an act of Congress authorizing the President of the United States to coordinate various related activities under the executive administration. The President himself, desirous as he may have been to include the health activities of the Children's Bureau under the Federal Security Administration, which now includes the United States Public Health Service and the Food and Drug Administration and a considerable number of other medical activities, found it impossible to get the Children's Bureau included under a single coordinated administration. Until that is done there will no doubt be a continuation of exactly this sort of performance—the performance of a bureaucracy which is autocratic in its methods, secret in its operations and astute besides.

When a matter of this kind comes before us, the editor of *THE JOURNAL* must be guided by the policies of the House of Delegates or by an action of the Board of Trustees. When the House of Delegates has not taken action between meetings of the Board of Trustees, an endeavor is made to secure the point of view of the Board of Trustees by correspondence. This matter, as you have heard, came up gradually. It developed in the form of a small appropriation, which then became a larger appropriation. It came in as an appropriation bill. The actions taken are not the actions of the Congress but the regulations of the Children's Bureau under advice of its solicitor, and leaning on its advisory committee. If you criticize them they say, "We were advised by the Advisory Committee, which included representatives of the medical profession. We thought we could take their advice."

Whether or not this is an entering wedge, a foot in the door for federalized medicine, I am not at all certain. I endeavor to observe trends in government and in legislation; I would emphasize Mr. Holloway's statement as to the action of the Appropriations Committee of the House of Representatives on Dr. Parran's request for \$1,000,000, and the positive statement of the Appropriations Committee that it did not believe in the use of federal funds to give medical care in the individual states, that that was a local responsibility. That seems to me to begin to represent the trend. The innumerable letters that have come from Senators and Representatives on this point also indicate a changing trend in thought, largely brought about, I believe, by activities of the medical profession in recent years. Equally a general resentment seems to be growing up through the United States to too much government interference in private life, no doubt justified by the war, but unquestionably bound to be resented at the earliest possible opportunity after the war. If you will observe the advertisements appearing in numerous magazines and newspapers, the editorials now being published and the cartoons, you will discover that there is a growing trend, a growing resentment, against too much federal interference in private life in the United States. Maybe if it grows enough eventually the Children's Bureau will be included where it belongs as a part of a single federal agency concerned with health.

DR. L. W. MASON, Denver: I too, like Dr. Rucker and perhaps several others in the audience, am one of those who, being endowed with less brains than the average man, in the course of time became an obstetrician. I don't care to go into the fee part of this maternal and child welfare bill in detail. I would like to say, regarding Colorado's attitude toward this, that last summer, as editor of the *Rocky Mountain Medical Journal*, I met with Dr. Cleere, the secretary of the state health board, who has the administration of this plan in Colorado, and with members of the Child and Maternal Welfare and Public Policy committees of the state medical society. Dr. Cleere had with him and gave to us a sheaf of papers about fifteen pages in length which embraced the provisions of this federal plan. Dr. Cleere had been told to, or had been given permission to submit a plan to the federal bureau of his own, and we presumed that what he would get back would be a compromise between what we had recommended and what had been proposed. After a considerable number of alterations, particularly in fees, and, as I say, I am not going to discuss individual fees in these remarks, the program was approved by the Public Policy Committee and by the Maternal and Child

Welfare Committee of the state medical society; to be brought up before the house of delegates, which didn't meet for about five or six weeks, for the approval of the state medical society. We did not get back from the Children's Bureau (or wherever it came from) a reply to our proposed proposition until after the state society met, and the state society through its house of delegates did ratify it, with the strict limitation that it was considered by the doctors who participated in it as strictly a patriotic measure and that it would not be approved for a period longer than six months after the emergency was over. The House of Delegates approved not what has been proposed but the schedule we have made, which involved some changes. After the house of delegates of the Colorado State Medical Society had met and approved what we proposed, we received back the plan from the Children's Bureau in practically the identical form we had received it before the meeting that night. One reason why Dr. Cleere was in a hurry at our meeting that night and said he could not wait to submit this until after the house of delegates met was the fact that his office was being besieged daily with dozens of applications from the wives of servicemen who had already found out—I won't say they had been told—but they all found out that they were to have this care, and his office was besieged all day long by expected recipients of this care, as to where to go to receive this manna from heaven.

Several times this morning we have heard speakers say they have been asked to serve in an advisory capacity to various governmental bureaus. If there has been any change in the activity of any bureau as a result of these advisory committees that we have furnished them, it has not been apparent in anything any one said to us this morning. As has been brought out very frequently, we are constantly put on the defensive in these matters because we don't know anything about them until after it is all done, and then it is too late to make any changes in the matter. It was pitiful to read in *THE JOURNAL* two or three years ago about our efforts to get somebody from the American Medical Association to represent the doctors on the Federal Planning Commission. We never did have a real invitation to that, and finally we were permitted to have some one there as an auditor. We had no voice whatever in the decisions that were made which affect us as the ultimate givers of the services involved.

I am firmly convinced that the time has come when there should be some change in the organization of the American Medical Association which will permit us to have some legally constituted bargaining agent whereby we can demand that we be given a voice in anything that affects us directly, and not be placed in the perpetual position as supplicants even for an auditor at these meetings which involve the services that you and I as individuals give. I would like to invite the editors and secretaries of this conference, who have a lot to do with molding the opinion of doctors throughout the country, to an editorial which I wrote and which is in the October number of the *Rocky Mountain Medical Journal* along those lines.

DR. P. T. TALBOT, New Orleans: Being one of the representatives of a black sheep state, so called because we were rather late in getting around to this proposition, I would like to have you recognize, Mr. Chairman, our distinguished president of the Louisiana State Medical Society, who is here and will tell you why we were so slow about adopting this measure. He is Dr. C. C. deGravelles, president of the Louisiana State Medical Society. I wish you would recognize him.

THE CHAIRMAN: The Conference recognizes Dr. deGravelles.

DR. C. C. DEGRAVELLES, New Iberia, La.: At the meeting of the Louisiana State Medical Society last April this proposition was put before the house of delegates. The house of delegates turned it down in toto; then they reconsidered and asked that the president appoint a committee to look into the matter. I appointed a committee composed of Dr. O'Ferrall as chairman, with two other members, and Dr. O'Ferrall did a wonderful piece of work. He contacted many other states and got their views. After going into the thing very thoroughly and we turned it down again. Then we got another plan. I called several meetings of the executive committee of the state, and each time it was turned down, until about six weeks ago we began to be really "worked on." I began to receive letters

from high officials wanting to know where the patriotism was of the doctors of Louisiana, because we were going back on the enlisted men. I had several letters from the American Legion, and we began to be criticized from all directions. We are having a governor's race in our state now, and the politicians began to jump on me. So I called another meeting of the executive committee and we accepted the proposal under protest. It is now before the Children's Bureau in Washington. We turned this down for several reasons, but one of the principal reasons was the "foot in the door" angle. It seems now that we have two feet in the door. At first it was the care of the obstetric end, but now, as I understand it, we are supposed to take care of any emergency that arises. Another factor that is worrying us very much in Louisiana is the fact that we have between 300,000 and 400,000 soldiers being trained there in our camps. We are extremely short of physicians. Louisiana has oversubscribed its quota in physicians to the Army. Conditions existing around those camps are not good. Around Alexandria the doctors are hardly able to take care of the civilian population. Now the soldiers' wives are drifting in. How the doctors are going to take care of them I do not know. The hospital facilities simply are not available. I have one friend who told me about 2 cases he had last week, which were delivered in a little one room shack with absolutely no help. Now the women are being left there. What is going to happen to those cases? We do not have the hospital facilities for them. I find that the doctors throughout the country are ignorant about this proposal. I believe we should tell our story to the American people through every available means. If the American Medical Association must forfeit its tax exemption status for the privilege of interpreting the medical profession to the American people let us get together and do something about it. I believe the American Medical Association should have an information bureau in Washington to maintain continuous communication between the medical profession and the people, between the agencies and legislation who are interested in the service that the American medical profession renders.

DR. ANDERSON: Mr. Chairman, I wouldn't have come to this platform if the name of Texas hadn't been drawn into this discussion, and the members of the conference are entitled to know its position, as far as the medical profession is concerned. Texas is one of those states which have been publicized far and wide as not having accepted the program of the Children's Bureau. The publicity which has come from the Children's Bureau, pointing out that Texas hasn't done so, has been hurtful to the medical profession of Texas. It has been that type of publicity. Actually the reason why that program is not operating in Texas as it is supposedly operating elsewhere is not the action of the State Medical Association of Texas but legal complications which have made it impossible for our state health officer to receive the moneys to be disbursed according to this program, or so it has been reported to us. Now, when those legal complications are done away with you are going to see the announcement in the public press that Texas has joined the vanguard and has this program in operation. Then again I want you to remember that it isn't going to be in operation in Texas with the approval of the State Medical Association of Texas, because the State Medical Association of Texas, through its executive council, has neither approved the plan officially nor disapproved it. It has done as we have heard discussed here—recognized that this program is another example of the socialization of medicine. To try to curb or stop some of the tendencies of various bureaus of the federal government in these "foot in the door" matters, our executive council meeting at Fort Worth on July 13 (and I am referring now to the threats to socialized medicine confronting us, such as the Farm Security Administration with its medical program, the Department of Agriculture with its experimental health program, the Children's Bureau with its maternalistic plan of paying the doctors directly for services to the wives and children of enlisted men in our armed forces and perhaps others)—adopted the following resolution:

Whereas, The medical profession as an organization is solicited and urged by various governmental agencies to enter into agreements and contracts sought to be made for the purpose of supplying the hospital and medical services to certain specified groups of our people; and

Whereas, We feel that all such agreements and contracts sought to be made by governmental agencies with the medical profession as an established organization would ultimately regiment medical services to the sick, if such contracts and agreements were agreed to and entered into by our profession as an organization; therefore, be it

Resolved, By the Executive Council of the State Medical Association of Texas, in called meeting this day assembled,

"First: That the State Medical Association of Texas, its component societies, committees, bureaus, representatives and officers be advised and directed, as such, not to sign or agree to any plan, agreement or contract sought for the purpose of providing hospital and medical care for any designated group or groups.

Second: That any physician as an individual is free to make any agreement or contract with any group, agency or organization for the purpose of rendering his medical care and services to any persons designated and agreed on. All fees and all terms of any contracts or agreements made and entered into to be decided and fixed by the physician as an individual and any agency or any authority which may be a party to the contract.

Third: The medical profession never has, does not now and never will seek to escape any duties or obligations. We yield to no group when loyalty and devotion are called on to protect the interest and welfare of our people

DR. C. N. JAEKEL, Detroit: It seems to me there is one point that should be cleared. I refer to the responsibility for what Dr. Foster has referred to as the edict of the Children's Bureau. Dr. Daily said they secured advice from the attorney general of the United States. We wrote to the attorney general of the United States and asked for a copy of that opinion, and he sent us an opinion to the effect on another point, namely to the effect that osteopaths could participate in this program. I would like to ask Dr. Daily if the opinion to which he referred, on the basis of which the Children's Bureau says the money cannot be paid to the women directly, is in writing?

DR. DAILY: Yes, the opinion from the solicitor of the Department of Labor is in writing. Of much more importance is the action of Congress during recent appropriation act discussions when the specific point was brought to its consideration, that is the amendment proposed to the House making the benefit payment to the wife. The House turned down that amendment.

DR. JAEKEL: That was a negative action of Congress, and it is reasonable. It denied and refused to accept something that was positive. The fact that Congress turned down the proposed amendment does not mean that it mandated that the money should be paid to the doctors.

DR. L. W. LARSON, Bismarck, N. D.: Representing a state in which the plan has been definitely turned down, I want to get into that select group of three states that do not want the president of the Louisiana State Medical Society to go home with the idea that there are only two states that have rejected the plan. You allowed yourselves to get into this mess. We turned it down, and fortunately we had enough friends in high places in our state who stood with us. As long as we have a governor who is a Democrat, a friend of the medical profession—he controls the state board of health; the chairman and the counsel of the state board of health is the chairman of our Committee on Maternal and Child Welfare; the state health officer depends for his livelihood on the appointment not only from the governor but on the recommendation of that counsel—as long as that state of affairs exists in our state we are not going to have a plan in operation in North Dakota that is not entirely acceptable to the profession of our state.

WOMAN'S AUXILIARY

Montana

The Woman's Auxiliary to the Silver Bow County Medical Society was organized recently. The organization meeting was presided over by Mrs. P. E. Logan, Great Falls, president of the Montana State Medical Association auxiliary. The following officers were elected: president, Mrs. Harold Schwartz; vice president, Mrs. T. J. B. Shanley; secretary, Mrs. P. E. Kane; treasurer, Mrs. C. B. Rodes.

North Carolina

The executive board of the North Carolina auxiliary met at the home of Dr. and Mrs. P. P. McCain at Sanatorium, October 14. Twenty-one members were entertained at luncheon.

North Carolina, under the direction of Mrs. B. W. Roberts, war participation chairman, plans to furnish thirty emergency medical kits to small ships of the Coast Guard and the Navy. It expects to help enlist nurses, interest members in first aid classes, Red Cross and other organizations connected with national defense, and have drives for surgical and medical supplies.

Pennsylvania

The Woman's Auxiliary to the Medical Society of Pennsylvania held its state convention recently in Philadelphia. Mrs. Charles G. Eicher, Mount Lebanon, state president, presided.

South Carolina

At the Pickens County medical auxiliary meeting recently plans for a county hospital were discussed, the new tuberculosis field worker talked of her work, and an informative article on penicillin was read.

The midyear executive board meeting of the South Carolina auxiliary convened in Greenville, October 13, with Mrs. J. E. Orr, president, presiding. The student loan fund, no longer needed since the government had taken over medical students, was turned into war bonds.

Texas

The Texas auxiliary is having well attended meetings in the various county auxiliaries. Mrs. A. B. Pumphrey of Fort Worth is president. In the Kerr-Kendall-Gillespie-Bandera Counties auxiliary twenty-one members reported that it had given 453 hours to Red Cross work during the summer. Tuberculosis Christmas seals were sold under the sponsorship of the Kerr County auxiliary. The Jefferson County auxiliary is giving one day a month to Red Cross work. The El Paso County auxiliary and Dallas County auxiliary are also active.

The executive board of the Texas auxiliary met recently in Fort Worth with Mrs. A. B. Pumphrey, state president, presiding. She gave an interesting address and stated her aims for the year. The auxiliary will sponsor an essay contest on the subject "Medical Science Fights at Home and Abroad." Members were urged to fight the Wagner-Murray-Dingell bill, and Dr. R. B. Anderson, guest speaker, gave four concrete ways in which the auxiliary could help the medical profession.

West Virginia

A special committee from the executive board of the Woman's Auxiliary to the West Virginia State Medical Association recently met with the Fact Finding and Planning Committee of the association in Huntington for the purpose of completing plans for a statewide educational program pertaining to constitutional government.

Mrs. V. E. Halcomb, Charleston, a past president of the national auxiliary, is chairman of the speaker's bureau for West Virginia.

The West Virginia auxiliary held its fall board meeting in Charleston recently, with twenty-two members present. It plans to publish a news letter, which will be sent to each member and to the doctors from West Virginia who are in military service.

Wisconsin

Mrs. L. H. Lokvam, president-elect of the Wisconsin auxiliary, was a guest of the Woman's Auxiliary to the Kenosha County Medical Society at its October meeting. Dr. C. C. Davis, president of the Kenosha Medical Society, spoke to the group on "Medical Legislation."

Ten past presidents of the Woman's Auxiliary to the Medical Society of Milwaukee County were hostesses at the opening luncheon and fall meeting at the City Club recently. The guest speaker was Dr. John F. Lundy, Rochester, Minn., who discussed "Painless Childbirth."

Fond du Lac, LaCrosse and Sheboygan auxiliaries also report interesting fall meetings.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Annual Course in Ophthalmology and Otolaryngology.

—The thirteenth annual midwinter postgraduate clinical convention in ophthalmology and otolaryngology, January 17 to 28, under the auspices of the Research Study Club of Los Angeles, has been designated the John Finch Barnhill Memorial Program in honor of the late Dr. Barnhill, who directed the program for so many years. A special course in "Applied Anatomy and Cadaver Surgery of the Head and Neck" will be given from January 28 to February 1. Among the lecturers will be:

- Dr. Georgiana M. D. Theobald, Oak Park, Ill., Anatomy and Histology of the Anterior Segment of the Eyeball with Special Reference to the Canal of Schlemm.
Dr. James Watson White, New York, Pathological Variations: Individual Muscles; Associated Movements; Convergence Divergence; Sursumvergence and Rotation.
Irving B. Lucke, M.S., Rochester, N. Y., Some Optics of Ophthalmic Lenses.
Dr. Meyer Wiener, Coronado, Calif., Surgery of the Eye.
Weston A. Price, D.D.S., Banning, Calif., Deficiency Diseases and the Eye, Ear, Nose and Throat.
Dr. Isidore Friesner, New York, Neoplasms Involving the Middle Ear.
Dr. Clinton H. Thienes, Los Angeles, Statistical Evaluation of Data Obtained in Experimental and Clinical Study.
Dr. Arthur W. Proetz, St. Louis, Common Misconceptions in the Management of Sinusitis.
Dr. Samuel Salinger, Chicago, An Analysis of Etiologic and Diagnostic Factors in Chronic Sinusitis.
Dr. Isaac H. Jones, Los Angeles, Vitamins and the Eye, Ear, Nose and Throat.
Dr. Paul M. Hamilton, San Marino, Calif., The Use of Penicillin in Ophthalmology and Otolaryngology.
Dr. Lawrence K. Gundrum, Los Angeles, The Effects of Sulfonamide Solutions on the Nasal Mucosa.
Dr. Carl H. McCaskey, Indianapolis, Ludwig's Angina.
Dr. Gordon B. New, Rochester, Minn., Laryngeal Lesions: Diagnosis and Treatment.

The annual meeting of the Los Angeles Society of Ophthalmology and Otolaryngology will be a feature of the meeting January 17, and on January 22 the western section of the American Laryngological, Rhinological and Otolological Society will hold its annual session.

CONNECTICUT

Clinics for Inebriates.—A diagnostic and guidance clinic for inebriates will be opened in New Haven in February under the joint sponsorship of the Yale Laboratory of Applied Physiology and the Connecticut Prison Association. A similar clinic will also be opened in Hartford in the near future. With the active participation of the Connecticut State Medical Society and religious and civic organizations, the clinics will deal with both the prevention and the control of inebriety. Their objectives will be to contribute toward the prevention of inebriety, to aid the inebriate to regain his usefulness in the community, to ease the economic burden imposed by present handling of inebriates, to ease crowding of prisons and jails, to serve as consultants to courts and welfare agencies, to serve as advisers to inebriates and their relatives, to acquaint the public in general with the medical aspects of inebriety and to serve as experimental models for future procedures, to train social workers in this field and to provide material for clinical-statistical research studies. The plan for the clinics was worked out in close cooperation with Chief Justice William M. Maltbie, Hartford, president of the Connecticut Prison Association, and their opening is assisted by a large contribution to the association by an anonymous Hartford donor. Each clinic will be staffed by psychiatrists, a psychologist, a social worker and a clerk, with representatives of Alcoholics Anonymous and the Salvation Army on call, and will work under the supervision of Elvin M. Jellinek, Sc.D., director of the School of Alcohol Studies, Yale Laboratory of Applied Physiology, the medical director of clinics and a legal consultant. According to a release from Yale University, the clinics will take advantage of the existing institutions of the state and serve as a clearing house for them. The creation of an institution for the treatment of inebriates at present is not contemplated, it was stated. Dr. Ralph S. Banay, psychiatric consultant of the New York State Parole Board and formerly chief psychiatrist of Sing Sing Prison, will be the medical

director and will supervise both the New Haven and the Hartford clinic. Dr. Clements C. Fry, New Haven, psychiatrist of the Yale Department of Health, will serve as adviser. Dr. Banay will also participate in the routine clinical work. Anna Roe, Ph.D., a member of the staff of the School of Alcohol Studies, will be in charge of psychologic testing, and Raymond G. McCarthy will have charge of the social work. The Hartford clinic will be served by a psychiatrist four days a week and the New Haven clinic three days a week. The social workers and clerks will serve full time at each clinic. Dr. Howard W. Haggard, director of the laboratory of applied physiology at Yale, who will be in general charge of the program, stated that these clinics are the first of the kind to be set up in this country. Persons referred to the clinic will be interviewed by the psychiatrist and investigated by the social worker. The psychiatrist's recommendations will be based on his finding as modified by a knowledge of the patient's personality, his family and employment relations and other factors. He may recommend court or voluntary commitment for treatment or contact with Alcoholics Anonymous or the Salvation Army and make the contact of special occupation or private treatment. No specific sanatorium or therapist may be named, but the patient will be given a list of sanatoriums and private practitioners specializing in the treatment of alcoholism approved by the Connecticut State Medical Society. Medical examinations will not be given at the clinics, but patients will be referred to practitioners selected from a panel prepared by the state medical society, the cost to be borne by the clinic. The advisory committee appointed by the state medical society is composed of Drs. Arthur B. Dayton, New Haven; Leslie R. Angus and Foster E. Priddy, Hartford; Louis H. Cohen, Norwich, and Francis M. Shockley, Stamford.

ILLINOIS

Dr. Sievers Named Chief of Communicable Diseases.

—Dr. Jerome J. Sievers, assistant state health director, has been appointed chief of the division of communicable diseases, effective January 1, succeeding the late Dr. John J. McShane. Dr. Sievers resigned as assistant director, a position which he had held since Sept. 1, 1943, to accept the new appointment. Dr. Sievers was graduated from the University of Illinois College of Medicine in 1935 and received his M.S. degree at the University of Michigan in 1939, the same year in which he joined the state department of health. Prior to his appointment as assistant state health director he served as assistant to the chief of the division of communicable diseases.

Cancer Forum.—The Chicago Cancer Committee, Inc., will sponsor a forum for residents of the North Shore suburbs at the Winnetka Community House, January 18. Dr. Irving S. Cutter, Wilmette, medical superintendent, Passavant Memorial Hospital, will be the moderator, and Dr. Ludvig Hektoen, chairman of the Chicago Cancer Committee, will make the introductory statement. Among the speakers will be:

- Dr. Bowman C. Crowell, The Course of Cancer.
Dr. Josiah J. Moore, The Causes of Cancer.
Dr. Herbert E. Schmitz, The Diagnosis of Cancer.
Dr. John A. Wolfer, The Curability of Cancer.
Dr. Frederick W. Merrifield, What the Patient Can Do About It.

The Winnetka forum will be the fourth arranged by the Chicago Cancer Committee for the public to give information about the curability of cancer when treated in an early stage.

Chicago

Births Set New Record at Chicago Lying-In.—The total number of deliveries at Chicago Lying-In Hospital and Dispensary of the University of Chicago was 3,813 during the year ended June 30, 1943, according to a recent release. The total, an increase of 11 per cent over the previous year, recorded an all time high for the institution for its forty-eight years' existence. The mortality among newborn infants was 3.1 per cent for babies who were either stillborn or died during the first two weeks of life.

Changes in the Faculty at Northwestern.—New appointments to the Northwestern University Medical School include Dr. Malcolm T. MacEachern to associate professor of medicine, Dr. Henry C. Sweany to associate professor of medicine, Dr. John Carroll McCarter to assistant professor of pathology and Chi Che Wang, Ph.D., to assistant professor of physiology. Recent promotions at the school include those of Drs. Abraham Levinson to associate professor of pediatrics, Frederick W. Merrifield to assistant professor of surgery and Leonard Cardon to assistant professor of medicine.

Chilean Visitors in Chicago.—Col. Flavio Meza Olva, prospective surgeon general of the Chilean army, and Major Ramon Vicuna Herboso, surgeon attached to the army headquarters, were accompanied by Capt. Gustave Freeman, M.R.C., Surgeon General's Office, Washington, D. C., on a tour of medical points of interest in Chicago, January 5-9. Among the places visited were the American Medical Association, American College of Surgeons, American Dental Association and the local medical schools. They were guests of the American Medical Association during its radio broadcast entitled "Doctors at War" over NBC on January 8.

Medical Missionaries Home on Gripsholm Honored.—A luncheon was held on January 7 at the Hotel LaSalle under the auspices of the Chicago Committees and the Christian Medical Council for Overseas Work to honor American missionary doctors and nurses just returned on the *Gripsholm*. Among those present were Drs. William W. Cadbury, Canton, China, Ernest H. Clay, Foochow, China, and John Horton Daniels, Nanking, China, and Johanna Margaret Friberg, R.N., Willie Pauline Harris, R.N., and Alice Maud Powell, R.N. Dr. Walter H. Judd, representative from Minnesota, was the guest speaker. Dr. Judd, who in 1942 received a medal "of honored merit" for wartime services to China, was formerly a missionary in China.

KANSAS

Dr. Mayes Joins Children's Bureau.—Dr. William Fred Mayes, Topeka, has resigned as director of the division of maternal and child welfare of the Kansas State Board of Health, effective Dec. 1, 1943, to become regional medical consultant for the Children's Bureau, Washington, D. C. Temporarily, Dr. Mayes is to be located in the Kansas City district. He has been director of the state division of maternal and child welfare since May 1, 1942.

The Porter Lectures.—Dr. Herbert M. Evans, director of the Institute of Experimental Biology, University of California, Berkeley, gave three lectures under the Porter Lectureship in Medicine at the University of Kansas School of Medicine, Lawrence-Kansas City, December 8-9. The titles of Dr. Evans lectures were "The Present Position of Our Knowledge of the Anterior Hypophyseal Hormones," December 8, "The Internal Secretions of the Pituitary Body: A Historical Resume," and "The Adrenotropic Hormone of the Anterior Hypophysis," December 9.

MARYLAND

New Director of Child Hygiene.—Dr. Dean W. Roberts, Baltimore, was recently appointed chief of the bureau of child hygiene of the Maryland State Department of Health. He succeeds Dr. Edward Davens, Baltimore, who was granted military leave on Oct. 11, 1943.

One Hundred and Fifty Years of Health.—The December *Baltimore Health News* commemorates the 150th anniversary of the founding of the public health service of the community, resulting in the present city health department. The first local health unit board was organized in Baltimore in 1793, announcing in that year that Baltimore is "free from the Yellow Fever." This fact has peculiar historical significance because of the epidemic of yellow fever among the 40,000 inhabitants in Philadelphia in that year, when a group of 4,044 died of yellow fever. *Baltimore Health News* carries the development of the board from its inception and touches on the organization of similar boards in Boston, Philadelphia and New York, recalling that the first president of the Boston town board of health in 1799 was the renowned Paul Revere. In 1793 "an act to appoint a health officer for the port of Baltimore-town, in Baltimore County" was prepared and now hangs in the state hall of records in Annapolis bearing the signature of the governor, Thomas Sim Lee, and the date of assent, Dec. 28, 1793. The act contains a section authorizing the erection of a temporary quarantine hospital, this probably stemming from the fear of yellow fever, which had been reported in Philadelphia and which subsequently caused a devastating epidemic.

MASSACHUSETTS

Boston Dispensary Offers Fellowships in Medicine.—The Boston Dispensary offers six fellowships in medicine in its clinics and domiciliary medical service for appointments immediately or before July 1. The fellowships are approved by the American Board of Internal Medicine in satisfaction of graduate training. Additional information may be obtained from Mr. Frank E. Wing, director of the Boston Dispensary, 25 Becket Street, Boston.

Personal.—Dr. Harvey Spencer, Wellesley, has resigned as acting director of the Habit Clinic for Child Guidance and as psychiatrist at the Judge Baker Guidance Center, Boston, to join the staff of the Austen Riggs Foundation, Stockbridge. —Dr. Valy Menkin, formerly assistant professor of pathology at the Harvard Medical School, Boston, is now associate in research at the Fearing Research Laboratory of the Free Hospital for Women, Brookline, where he will continue his studies in general pathology with particular emphasis on inflammation and cancer research.

Children's Clinic Named for Physician.—The new Southard Clinic for Children and Adults was recently opened in Boston under the auspices of the Massachusetts Department of Mental Health. The clinic is a memorial to the late Dr. Elmer E. Southard, first director of the Boston Psychopathic Hospital in 1912. Dr. Harry C. Solomon, recently appointed professor of psychiatry, Harvard Medical School, Boston, was chosen medical director to organize the clinic and is assisted by Drs. Oscar J. Raeder and Edgar C. Yerbury as co-directors. According to the *Monthly Bulletin* of the state society for mental hygiene, the present staff of the clinic comprises five psychiatrists, one neurologist, six psychologists and nine psychiatric social workers. The clinic fulfils the need of a mental hygiene center for children and adults. It is an outpatient unit equipped with modern facilities for study and treatment of psychiatric and neurologic conditions. It functions as a psychiatric teaching and training center for members of the medical, nursing and psychiatric social work professions.

MICHIGAN

Students Win Scholastic Awards.—At the commencement exercises of Wayne University College of Medicine, Detroit, December 9, the distinguished service award given to the student outstanding in scholarship and extracurricular activities went to Dr. Steven E. Staryk, Detroit, president of the Student Council. The Alumni Award, presented to the student who has maintained the highest scholastic standing during his four years in the college, was given to Dr. Oscar J. Balchum, Detroit.

Personal.—Orin E. Madison, Ph.D., Detroit, has been reelected president of the Board of Examiners in the Basic Sciences for the State of Michigan. Arthur M. Chickering, Ph.D., Albion, was elected vice president. —Drs. Robert L. Schorr and Otto T. Toepel, Detroit, who are honor members of the Wayne County Medical Society, have been elected to emeritus membership in the Michigan State Medical Society. —Harold S. Adams, Ph.D., recently chosen vice president and director of production of the Upjohn Company, Kalamazoo, died December 4.

MINNESOTA

County Society Plans Group Annuities.—A group plan combining low cost life insurance annuities for members wishing to participate has been recommended for acceptance to its members by the board of directors of the Hennepin County Medical Society. A basic policy of \$5,000 insurance and an annuity at \$50 per month at age 65 is a feature of the plan, members to purchase additional units as desired.

Special Society Elections.—Dr. Walter P. Gardner, St. Paul, was elected president of the Minnesota Society of Neurology and Psychiatry at a meeting in Minneapolis November 12. Dr. James W. Kernohan, Rochester, vice president and Dr. Royal C. Gray, Cambridge, secretary-treasurer. Dr. Kernohan discussed "Healing of Brain Wounds" at the meeting and Dr. Joseph C. Michael, Minneapolis, "Acute Ascending (Landry's) Paralysis." —Dr. Bayard T. Horton, Rochester, was elected president of the Minnesota Society of Internal Medicine at its recent annual meeting in St. Paul.

Continuation Course in Otolaryngology.—The Center for Continuation Study at the University of Minnesota, Minneapolis, announces a continuation course in otolaryngology for physicians who limit their practice to ophthalmology and otolaryngology, February 7-11. Registration will be limited to 50 physicians. The faculty will include:

Dr. Oscar V. Batson, assistant professor of otolaryngology, University of Pennsylvania School of Medicine, Philadelphia.

Dr. Paul H. Holinger, associate in laryngology, rhinology and otology, University of Illinois College of Medicine, Chicago.

Dr. John R. Lindsay, professor of surgery, department of otolaryngology, University of Chicago School of Medicine.

Dr. Theodore E. Walsh, professor of otolaryngology, Washington University School of Medicine, St. Louis.

Dr. Lawrence R. Boies, clinical associate professor of otorhinolaryngology, University of Minnesota Medical School, Minneapolis.

Additional information may be obtained from the Center for Continuation Study, University of Minnesota, Minneapolis 14.

NEW JERSEY

Rotarians Serve as Hospital Helpers.—The Rotary Club of Elizabeth recently created a system of "volunteer corpsmen" who work in the emergency and operating rooms at the local hospital as well as with the ambulance detail. The system was worked out to overcome the manpower shortage at the hospital. The Rotary Club named a committee, made the activity communitywide, lined up 30 volunteer "corpsmen" and then outlined long range plans for training classes to take care of additional volunteers. The men work in three shifts that run from 7 a. m. to 11 p. m. and, according to the *Rotarian*, "lift, carry, push and shove heavy hospital equipment. They bring patients to the operating room, stand by as anesthesia is administered, manipulate the lights needed by the surgeon, return the patient to his bed and then come back to mop up the floor. They drive the ambulance, handle its passengers. They operate laundry equipment. They help out in the mental hygiene ward. And in addition should any major disaster, such as an air raid, a plant explosion or a transportation smash-up, put an added burden on the hospital's facilities, the 'corpsmen' are pledged to put in needed 'emergency hours' to help out." The plan started when a hospital superintendent, a member of the Rotary Club, discussed the shortage of help, particularly with heavy work, at the hospital during a meeting of the Rotary Club.

NEW YORK

Personal.—Dr. Mark D. Doby has been appointed health officer of Schuylerville. —Dr. Hugh H. Shaw on January 1 entered his twenty-fifth year as health officer of Utica. —Dr. Terry S. Montague, Gouverneur, has been appointed health officer of Watertown, succeeding Dr. George B. Van Doren, retired.

Canvass of Home Accidents.—As a part of an educational program the State Home and Farm Safety Advisory Committee is collecting information on the statistics of non-fatal home accidents through the cooperation of volunteer canvassers and householders in a house to house canvass of home accidents. The cities of Oneida, Saratoga Springs and Oswego have already submitted reports, and the canvass is in progress in fifteen other cities. According to *Health News*, steps are being taken in the larger cities to organize a canvass on a basis of a cross section of the population, the project to be continued throughout the winter and early spring. No names of individuals are entered on the record forms, but there apparently is little or no reluctance to report an accident or even to take the blame for it if a human factor was in any way responsible. The most unusual and costly accident thus far reported was the explosion of a can of lye, *Health News* stated. The extensive burns which resulted required plastic surgery, and the cost of hospital and medical care ran into several thousand dollars. The accident was believed to have been caused by a manufacturing defect. Stepping on broken glass left on the floor in the dark caused an accident which resulted in the longest period of invalidism reported. When the survey is completed the statistics will be analyzed by the National Safety Council, which recommended the project, and the results will be used for national and state guidance in home accident prevention. The state department of health and the office of civilian mobilization of the state war council are sponsoring the project.

New York City

Psychiatrist Addresses Public Meeting.—Dr. Walter S. Maclay, medical officer in charge of the Mill Hill Emergency Hospital, London, addressed an open meeting on January 3 sponsored by the Medical Society of the County of Kings, the Brooklyn Chapter of the American Red Cross and the Brooklyn Council for Social Planning. Dr. Maclay discussed the treatment of war neurosis in Britain.

Dr. H. C. Taylor Appointed Chairman of Obstetric Department.—Dr. Howard C. Taylor Jr., associate professor of gynecology and obstetrics, New York University College of Medicine, since 1935, has been appointed chairman of the department of obstetrics and gynecology at the school. Dr. Taylor, who is associate editor of the *American Journal of Obstetrics and Gynecology*, graduated at the Columbia University College of Physicians and Surgeons in 1924.

Conference of Tuberculosis and Health Association.—The annual conference of the New York Tuberculosis and Health Association will be held at Hotel Pennsylvania on Wednesday, February 2. There will be morning section meetings on tuberculosis, the heart diseases, social hygiene and dental health in industry. The meeting on heart diseases will

be held at Hotel Governor Clinton. At a luncheon meeting in the Hotel Pennsylvania the speakers will be Rear Admiral Charles S. Stephenson (MC), U. S. Navy, and Sir Gerald Campbell, British minister in Washington and special assistant to the British ambassador.

Offers Plan to Eliminate Medical "Kickbacks."—A plan to eliminate "kickbacks" to physicians was outlined on December 15 to the Moreland Commission inquiring into alleged abuses in the administration of the workmen's compensation act by Dr. David J. Kaliski, chairman of the workmen's compensation boards of the Medical Society of the County of New York and of the Medical Society of the State of New York. According to the *New York World-Telegram* Dr. Kaliski first told the commissioners that more than 500 cases of alleged fee splitting had been investigated to date by the county society. Although no action had been taken, he is reported to have said that there "will have to be a number of trials." He advocated the sending of a joint itemized bill by physicians and specialists working on the same case "indicating how much each doctor would receive." One commissioner is reported to have observed that the plan seems "just a device for legalizing kickbacks." Dr. Kaliski, in reply, said that his plan was "the very opposite of kickbacks," asserting that such a plan is needed, particularly among the lower income groups in which the surgeon's fee, "usually rather high," is paid, whereas the family doctor often waits in vain for his payment.

Inter-Racial Policy Adopted at Sydenham Hospital.—A voluntary inter-racial policy has been adopted by Sydenham Hospital, providing for the first time in Harlem this type of hospital having all the rights and privileges of other voluntary hospitals in New York, such as tax exemption, support by the city, support from the Greater New York Fund and United Hospital Fund, and taking its place on a parity with New York's eighty-six other voluntary hospital institutions. The hospital will be staffed by Negro as well as white persons and directed by a hospital board composed of Negro and white persons. The new policy assures the use of the hospital facilities to all persons regardless of race, religion or national origin. It will be so organized as to provide qualified Negro physicians through staff positions with opportunities to hospitalize and care for their own patients and to improve their own medical competence. Private or ward accommodations will be provided according to the patient's ability to pay. According to a release, this hospital will become the first hospital which adheres to and proclaims the principle of inter-racial equality in hospital service in all its phases. The organization committee of the project is sponsored by the New York Urban League, Inc. Under the plan there will be no limitation on the number or quota of Negro physicians who may become attached to the staff. The present staff of the Sydenham Hospital will remain, it was stated. The group also plans to work toward the integrating of Negro medical, nursing and technical personnel into all hospitals in New York City.

OHIO

Walter Hartung New Health Director of Toledo.—Dr. Walter H. Hartung, in 1940 acting city health director and for some time associated with the Toledo Board of Health, has been appointed health officer, succeeding Dr. Earl E. Kleinschmidt, resigned. The change was effective on December 1, newspapers reported. Dr. Kleinschmidt had held the position since Nov. 1, 1942. Dr. Hartung, who formerly was state health officer, for some time had been superintendent of medical relief bureau in the city health department.

Museum Establishes Award for Health Education.—The "Elizabeth Severance Prentiss Award for Outstanding Contributions to Health Education" has been established by the Cleveland Health Museum in honor of Mrs. Prentiss, who in 1940 gave her childhood home to house the museum. Mrs. Prentiss died, January 4, at her home in Glenallen, Cleveland, at the age of 79. Her gifts to hospitals, including St. Luke's Hospital, Cleveland, and the Allen Hospital, Oberlin, were in memory of her first husband, Dr. Dudley Peter Allen, who died in 1915. In Cleveland, the Allen Memorial Medical Library is another institution founded by her in his memory. The first recipient of the award will be announced at the fourth annual meeting of the museum, in November 1944. The creation of the award was announced as a feature of the third anniversary of the museum, Nov. 22, 1943, at which Dr. James A. Doull, professor of hygiene and public health, Western Reserve University School of Medicine, Cleveland, spoke on

His work ranks him with his great predecessors of the Royal Society: Boyle, Hooke, Mayow, Lower, Hales, Priestley and John Scott Haldane, who received the Copley medal nine years ago. It was by the work of these men that our knowledge of the changes which occur in respiration was built up. The influence of Barcroft's researches has extended to physiologists all over the world, and they have become the starting point of further work.

PALESTINE

(From Our Regular Correspondent)

Oct. 29, 1943.

Palestine's Gift to Soviet Russia

Having overcome all the various difficulties which had for many weeks held up shipment of ambulances and medical supplies to Soviet Russia, the V League in Palestine was able recently to dispatch a second shipment to Teheran. The first shipment contained quantities of bromides, absorbent cotton and vaccines, while the second included (1) three ambulances, one of them being a mobile field hospital, each complete with medical and sanitary equipment for 14 beds (the equipment consisting of 42 articles totaling 1,280 items), (2) 1 ton of bromides, (3) two hundred thermometers, (4) sets of surgical instruments, (5) olive oil and phenolated soap, (6) two typewriters and (7) two fonts of linotype intended for use by the Jewish Anti-Fascist Committee in Kubeishov. The two typewriters are the gift of the General Federation of Jewish Labor in Palestine. The linotype equipment is the gift of the V League in Palestine.

Tuberculin Test of All Personnel Engaged in Children's Houses

The Anti-Tuberculosis League, the Hadassah Medical Association and the Kupat Holim (Workers' Sick Fund of the General Federation of Jewish Labor in Palestine) have recently intensified their efforts to combat tuberculosis in this country. An investigation was conducted by two Kupat Holim physicians, Dr. Hupert and Dr. Nassau, in the agricultural cooperative settlements among personnel in charge of the care and health of children, which revealed that 94.2 per cent were completely healthy, 2.7 per cent had inactive tuberculosis, another 2.7 per cent, though affected and in need of observation, did not require treatment, and 0.4 per cent were tuberculous and did require treatment. This proportion of affected persons is somewhat lower than in other countries, according to the published figures. The reason probably lies in the fact that the bulk of the persons examined in this investigation had been living a rural life for a considerable time and that their ages ranged between 16 and 30.

Bean Disease (Favism)

Favism is a disease which appears in the form of typical attacks of acute hemolytic anemia. Whenever a particularly sensitive person comes into contact with fave beans—at present their pathogenicity is explained by the allergic theory—he shows signs of the disease, either as the result of having eaten the beans or of having inhaled the pollen at the time of flowering. The pathogenic principle remains in the dried bean as well, even after prolonged cooking.

The first case of favism here was brought before Dr. Shieber at Beilinson Hospital, a Kupat Holim institution. Later, Dr. Robinson reported 3 cases seen in the Hadassah Hospital, and Dr. Genezzani of the Children's Department in the Hadassah Hospital in Tel Aviv has recently published an article in *Refuah* on 10 cases which he has treated in the past three years.

The disease was known in ancient times in all Mediterranean countries, but systematic, scientific investigation did not begin until the second half of the last century. Physicians of the Italian islands of Sardinia and Sicily were the first to carry

out these investigations and thought that the disease was restricted only to these places. But with the increased interest in favism among the physicians of other countries it was found that the disease is spread to all Mediterranean countries, including Palestine.

Statistical investigations showed that the disease affects chiefly males (80 per cent), that it is chiefly a disease of children, that most cases occur in the spring, that it is more common among certain races (Arabs and related races, Sephardic Jews, Yemenites) than others, and that, finally, it has some connection with malaria.

The disease usually has a benign course; the attack passes in about a week with complete recovery by means of active regeneration of the hemolyzed blood, though fatal cases have been reported. The most effective form of treatment is blood transfusion.

Scientific Conferences

At an all Palestine Conference of Children's Doctors, which took place in March, the principal subjects under discussion included chemical treatment of stomach and intestinal diseases in children, allergic skin diseases in children, bronchial asthma in children, cryptorchism and problems of toxicosis. A number of military doctors participated in the discussion and read papers on infectious diseases of the brain in children and neurosis in children. The lectures on chemical treatment of stomach and intestinal diseases emphasized the great value of sulfathiazole and sulfaguanidine in the treatment of diarrhea and toxicosis in children. Mortality among children from this disease has dropped from 50 per cent to 11.7 per cent as a result of these drugs. The doses were 0.1 Gm. per kilogram of the patient's weight daily for a period not exceeding five to eight days.

In June 1943 a Dermatologists' Conference was held, and the main subjects discussed were, among others, the physiology of the vitamin B complex, avitaminosis, allergy of the skin, the treatment of syphilis and leishmaniasis of the skin.

Shortage of Physicians and Nurses in Palestine

The shortage of physicians and nurses has recently become acute. One of the main reasons for this situation is the fact that many have volunteered for the various military services. Up to the present time, over two hundred Jewish doctors have joined the British army, and many more are waiting to be called.

Jewish doctors in Palestine are enlisting for all the services, including combatant units, as well as for service throughout the British Empire, Abyssinia, India and elsewhere. The volunteers include a large number of physicians on the permanent staffs of Kupat Holim and Hadassah. Twenty-five of these were attached to Kupat Holim alone.

The shortage of nurses, and particularly of midwives, is even more serious. The nonavailability of nurses is seriously impeding the extension of medical institutions, especially of Kupat Holim, which has opened new wings during the past year (30 surgical beds at Petach Tikva, 30 beds for maternity cases in Rehovoth, a new children's department of 40 beds in the Afuleh Hospital and the addition of 20 beds to the department for internal diseases at the Beilinson Hospital).

The nurses' schools attached to the Hadassah and Beilinson hospitals have accepted an increased number of students, and a number of new schools for nurses will shortly be opened in other hospitals. In the meantime the medical institutions are compelled to take on some nonqualified nurses.

The large scale enlistment of the Jewish community in Palestine (20,000 soldiers and A. T. S. serving with the army and 10,000 in the defense forces of Palestine) has made itself felt in all spheres of life and work in the country. Not only professions and trades but even unskilled labor are affected. Nevertheless the people, and among them the physicians, continue to volunteer.

Deaths

Alexander Earle Horwitz, St. Louis; Washington University School of Medicine, St. Louis, 1904; instructor in orthopedic surgery, St. Louis University School of Medicine, from 1910 to 1913, assistant professor from 1913 to 1933 and since the latter year associate professor of orthopedic surgery; member of the Clinical Orthopaedic Society and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; major, medical reserve corps, U. S. Army, not on active duty; assistant orthopedic surgeon, O'Fallon Dispensary, from 1908 to 1910, and the Washington University Hospital, 1909-1910; orthopedist, St. Louis City Hospital, since 1910 and Rebekah Hospital from 1910 to 1914; associate orthopedist, St. John's Hospital, from 1912 to 1926 and since 1926 orthopedist; visiting orthopedist, Robert Koch Hospital; orthopedist, St. Anthony's Hospital from 1921 to 1928 and St. Mary's Group of Hospitals since 1924; director of orthopedics, St. Louis City Hospital for the Colored, since 1935; assistant orthopedic surgeon from 1911 to 1916 and since 1927 associate orthopedist, Jewish Hospital, where he died November 30, aged 65, of pyelonephritis.

Georgine Maria Luden ✶ Victoria, B. C., Canada; Ludwig-Maximilians-Universität Medizinische Fakultät, Munich, Bavaria, Germany, 1912; member of the Minnesota State Medical Association, American Association for Cancer Research, Association for the Study of Internal Secretions, Medical Women's International Association, American Association for the Advancement of Science, International Association of Medical Museums and the Association of Resident and ex-Resident Physicians of the Mayo Clinic; formerly associate in cancer research at the Mayo Clinic, Rochester, Minn.; received a Ph.D. in pathology from the University of Minnesota in 1920; died November 20, aged 68, of carcinoma of the lung and tuberculosis.

Charles Curtis Jones ✶ Cincinnati; Ohio-Miami Medical College of the University of Cincinnati, 1910; specialist certified by the American Board of Otolaryngology; at one time assistant professor of otolaryngology at the University of Cincinnati College of Medicine; member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otolological Society; fellow of the American College of Surgeons; in charge of the medical division of civilian defense for Norwood and for many years a member of the board of health; served on the staffs of the Christ Hospital, Children's Hospital and the Bethesda Hospital, where he died November 22, aged 56, of pneumonia.

Dexter D. King ✶ York, Neb.; University of Nebraska College of Medicine, Omaha, 1914; past president of the Nebraska State Medical Association and the York County Medical Society; for one year honorary president of the Elkhorn Valley Medical Association; formerly councilor of the Sixth District Medical Society; served during World War I; for one term a member of the school board; affiliated with the York Clinic; on the staff of the Lutheran Hospital; president of the local Rotary Club, 1930-1931; served as a national director of the alumni association of the University of Nebraska; died November 27, aged 59, of cardiovascular renal disease.

George Buchanan Kryder ✶ Glendale, Calif.; University of Illinois College of Medicine, Chicago, 1920; specialist certified by the American Board of Pediatrics, Inc.; member of the American Academy of Pediatrics; child hygiene physician, health department of Los Angeles County; served in the medical corps of the U. S. Army during World War I; on the staffs of the Los Angeles County and Children's hospitals, Los Angeles, Physicians and Surgeons Hospital and the Glendale Sanitarium and Hospital; died November 19, aged 50, of coronary thrombosis.

Franklin Davis Wilson ✶ Norfolk, Va.; University of Maryland School of Medicine, Baltimore, 1908; specialist certified by the American Board of Pediatrics, Inc.; member of the American Academy of Pediatrics; fellow of the American College of Physicians; past president of the Norfolk County Medical Society; also a pharmacist; at one time a member of the county school board; on the staffs of the St. Vincent's Hospital, Leigh Memorial Hospital and the Norfolk General Hospital, where he died November 17, aged 61, of cerebral hemorrhage.

James Anthony Bach ✶ Milwaukee; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1884; formerly professor of ophthalmology and otology, Wisconsin

College of Physicians and Surgeons and the Marquette University School of Medicine; fellow of the American College of Surgeons; served on the staff of St. Mary's Hospital, where he died November 29, aged 83, of cerebral thrombosis.

Orrie Hugh Ball, Dennis, Kan.; University Medical College of Kansas City, Mo., 1900; member of the Kansas Medical Society; on the staffs of the Mercy Hospital, Parsons, and the Johnson Hospital, Chanute; died November 2, aged 72, of generalized arteriosclerosis.

Roger Biswell, Baker, Ore.; Willamette University Medical Department, Salem, 1906; member of the Oregon State Medical Society; served during World War I; on the staff of St. Elizabeth Hospital, where he died November 12, aged 62, of angina pectoris.

Walter T. Christensen, Seattle; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1905; member of the Washington State Medical Association; for five terms a member of the state legislature; formerly on the staffs of the Providence and Columbus hospitals; died November 10, aged 65, of cerebral hemorrhage.

Walter Roy Liddell Coakley, Buffalo; Albany (N. Y.) Medical College, 1913; on the staff of Our Lady of Victory Hospital, Lackawanna; died November 3, aged 57, of cirrhosis of the liver.

Lewis Morgan Daniel ✶ Minneapolis; University of Minnesota Medical School, Minneapolis, 1923; formerly secretary-treasurer of the Hennepin County Medical Society; served on the staff of the Abbott Hospital; died in Pompano, Fla., November 23, aged 49, of aortic stenosis.

William Dietz, Rockford, Wash.; Atlanta College of Physicians and Surgeons, 1902; died October 15, aged 66, of pulmonary edema and hypertensive heart disease.

George W. Fahrenbach, Bernville, Pa.; Baltimore (Md.) Medical College, 1900; member of the Medical Society of the State of Pennsylvania; member of the county and borough school boards and the local draft board; died November 13, aged 70, of carcinoma.

Elman Parker Felch, Centerville, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1893; died November 8, aged 76, of uremia.

Eldon Marshall Findley ✶ Graham, Mo.; Harvard Medical School, Boston, 1916; formerly instructor in physiology at the University of Missouri School of Medicine, Columbia; on the staff of St. Francis Hospital, Maryville; died November 18, aged 62, of coronary thrombosis.

Arthur Emile Gadbois, Norfolk, Neb.; John A. Creighton Medical College, Omaha, 1903; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; served as ophthalmologist for the Chicago and Northwestern Railway Company; a captain in the medical corps of the U. S. Army during World War I; on the staffs of the Lutheran and Our Lady of Lourdes hospitals; died November 19, aged 68, of coronary embolism.

James Arthur Gage, Lowell, Mass.; Harvard Medical School, Boston, 1885; member of the Massachusetts Medical Society and the New England Surgical Society; fellow of the American College of Surgeons; member of the House of Delegates of the American Medical Association in 1908 and 1910; served on the staff of the Lowell General Hospital; died November 29, aged 85, of pneumonia.

John Augustus Herring ✶ St. Petersburg, Fla.; University of Michigan Medical School, Ann Arbor, 1916; member of the Radiological Society of North America, Inc.; served as chief of staff, St. Anthony's Hospital; died November 17, aged 52, of coronary occlusion.

John Inglis ✶ Denver; Ohio Medical University, Columbus, 1895; Rush Medical College, Chicago, 1896; formerly member of the state board of medical examiners; author of "Chemistry in Abstract" (Encyclopedia Americana), Peking, 1906; on the staffs of the Mercy Hospital, St. Luke's Hospital and the Porter Sanitarium and Hospital, where he died November 20, aged 74, of pneumonia.

John Barlow James ✶ Page, N. D.; Northwestern University Medical School, Chicago, 1911; elected president of the Cass County Medical Society; served on the staffs of the Mercy Hospital, Valley City, Union Hospital, Maysville and St. John's Hospital, Fargo; died November 8, aged 56, of hypertension and cerebral hemorrhage.

William K. Jones, Wilmore, Ky.; Hospital College of Medicine, Louisville, 1897; member of the county health board; died in the Good Samaritan Hospital, Lexington, November 10, aged 71, of carcinoma of the prostate.

Jule Harrison Keller ☉ Lancaster, Mo.; Central Medical College of St. Joseph, 1900; served as county health officer; for six years county coroner; died November 23, aged 66, of heart disease.

Harry Thomas King, Minneapolis; Marquette University School of Medicine, Milwaukee, 1924; member of the Minnesota State Medical Association; examining physician, Hennepin County local draft board number 17; on the staff of the Lutheran Deaconess Home and Hospital; on the advisory board, member of board of governors and on the staff of St. Mary's Hospital, where he died October 10, aged 48, of fibrillation of the heart.

Lovick Pierce Longino, Milledgeville, Ga.; Atlanta College of Physicians and Surgeons, 1905; member of the Medical Association of Georgia and the American Psychiatric Association; recently resigned as superintendent of the Milledgeville State Hospital; died in the Emory Hospital, Atlanta, November 20, aged 64, of coronary occlusion.

Edwin Horner Lowe, Maryville, Tenn.; Medical Department of the Western University of Pennsylvania, Pittsburgh, 1892; member of the Medical Society of the State of Pennsylvania; veteran of the Spanish-American War; for many years physician for the Aluminum Company of America at Alcoa; died November 8, aged 73, of leukemia and intestinal hemorrhage.

Max Lubman, New York; Cornell University Medical College, New York, 1900; member of the American Academy of Ophthalmology and Otolaryngology; served in the outpatient department of the Mount Sinai Hospital; died November 20, aged 67, of coronary thrombosis.

Frederick Joseph Mayer, Opelousas, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1883; member of the Louisiana State Medical Society and president, 1913-1914; served as president of the Attakapas Medical Society, the oldest medical society in the state, in 1885; formerly special medical inspector for the Louisiana and Texas state boards of health; died December 1, aged 84.

William Taylor Miles, Louisville, Ky.; Louisville Medical College, 1892; member of the Kentucky State Medical Association; on the visiting staffs of St. Anthony's Hospital, Methodist Deaconess Hospital and the SS Mary and Elizabeth Hospital, where he died November 7, aged 75, of uremia.

James R. Miller, Stowell, Texas; Memphis (Tenn.) Hospital Medical College, 1897; died November 11, aged 75, of carcinoma of the neck and face.

Frederick R. Moessner, Madison, Wis.; Northwestern University Medical School, Chicago, 1904; died November 22, aged 66, of heart disease.

David Hubbell More, Long Beach, Calif.; Columbia University College of Physicians and Surgeons, New York, 1907; member of the California Medical Association; died in Beverly Hills, November 4, aged 65, of uremia due to carcinoma of the bladder.

David Hervey Morgan, Akron, Ohio; University of Wooster Medical Department, Cleveland, 1896; secretary of the Summit County Medical Society in 1912, vice president in 1913 and president in 1914; died in the Fair Oaks Villa Sanitarium, Cuyahoga Falls, November 11, aged 78, of cerebral hemorrhage.

Carlton D. Morris, Pontiac, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1894; at one time assistant in physiologic chemistry at his alma mater; formerly president of the Rotary Club; served on the staff of the Pontiac General Hospital, where he died November 28, aged 73, of carcinoma of the sigmoid with metastases.

Ralph Edward Munden, Cedar Rapids, Iowa; Milwaukee Medical College, 1909; member of the Iowa State Medical Society; died November 15, aged 56, of pneumonia and peritonitis.

Eryl Smith Peterson ☉ Jackson, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1907; served during World War I; past president of the Jackson County Medical Society; a member of the board of directors of the Ben Franklin Savings and Loan Association; died in Bradenton, Fla., November 17, aged 60, of coronary occlusion and arteriosclerosis.

William Peter Reckley, Youngstown, Ohio; Eclectic Medical College, Cincinnati, 1928; member of the Ohio State Medical Association; died in the Youngstown Hospital, North Side Unit, November 29, aged 40, of carcinoma.

Thomas Wesley Rennie, Chicago; Chicago College of Medicine and Surgery, 1917; died in the Veterans Administra-

tion Facility, Hines, Ill., November 29, aged 69, of hypertensive and coronary arteriosclerotic heart disease.

James Micaga Ringo, Houston, Texas; University of Louisville (Ky.) Medical Department, 1887; died October 28, aged 84, of pneumonia.

George Clovis Robert, Rossford, Ohio; McGill University Faculty of Medicine, Montreal, Que., Canada, 1897; served during World War I; formerly fire commissioner, and city physician of Holyoke, Mass.; at one time on the staffs of the Holyoke and Providence hospitals, Holyoke; died November 5, aged 70, of intestinal obstruction.

Isaac Poitevint Robinson, Shreveport, La.; Baltimore Medical College, 1897; at one time on the staff of St. Joseph's Hospital, Baltimore; died in a local sanatorium November 25, aged 82, of injuries and shock received when struck by a truck.

John Paul Rutherford, Bennington, Okla.; Chattanooga (Tenn.) Medical College, 1903; veteran of the Spanish-American War; died October 31, aged 63.

Gordon Joel Saxon ☉ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1908; died in Carbon Run, Pa., October 20, aged 64, of cirrhosis of the liver.

James Edgar Shepherd, Hope Mills, N. C.; University of Louisville (Ky.) Medical Department, 1885; veteran of the Spanish-American War; died in the Presbyterian Hospital, New York, November 16, aged 81, of senile cataract and bronchopneumonia.

Louis Sam Smith ☉ Brooklyn; Long Island College Hospital, Brooklyn, 1920; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; died October 23, aged 47, of brain tumor.

David Emmet Stafford, San Francisco; University of California Medical Department, San Francisco, 1903; member of the California Medical Association; for many years on the staff of St. Joseph's Hospital; died September 24, aged 65, of coronary disease.

Augustus Willard Tarr ☉ Johnston City, Ill.; Barnes Medical College, St. Louis, 1898; died November 23, aged 78, of cerebral hemorrhage.

Augustus Jerome Thomas, Shreveport, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1900; died October 31, aged 65.

Sidney Welles Thompson, Owego, N. Y.; University of the City of New York Medical Department, New York, 1896; member of the Medical Society of the State of New York; formerly mayor and village president; served during World War I; died in the Tioga County General Hospital, Waverly, October 29, aged 70, of cerebral thrombosis and arteriosclerosis.

DIED WHILE IN MILITARY SERVICE

Seale Harris Jr., Birmingham, Ala.; Johns Hopkins University School of Medicine, Baltimore, 1926; member of the Medical Association of the State of Alabama and the American Society for Clinical Investigation; fellow of the American College of Physicians; at one time assistant professor of medicine at the Vanderbilt University School of Medicine, Nashville, Tenn.; served as visiting physician at the Hillman and Baptist hospitals; major, medical corps, Army of the United States; for seven months head of an army base hospital in the Fiji Islands; second in command of an army base hospital in Brisbane, Australia; died in Brisbane, December 22, aged 43, of heart disease.

Joseph Eugene Seliady, Northville, Mich.; Detroit College of Medicine, 1932; member of the Michigan State Medical Society; served on the staff of the East Lawn Sanatorium; commissioned a captain in the medical corps, Army of the United States, on May 21, 1942 and recently promoted to major; died in Fort Sam Houston, Texas, November 19, aged 41, of peritonitis resulting from a bite.

Charles LaFayette Stevens ☉ Elmira, N. Y.; University of Buffalo School of Medicine, 1927; diplomate of the National Board of Medical Examiners; commissioned a lieutenant in the medical corps of the U. S. Naval Reserve on Feb. 11, 1941 and lieutenant commander on Oct. 1, 1942; died in the U. S. Naval Hospital, Pensacola, Fla., November 19, aged 39, of acute yellow atrophy of the liver.

Correspondence

"HAZARDS OF EXPOSURE TO GLASS" WOOL, GLASS FRIT OR FOAM GLASS"

To the Editor:—This letter is written to comment on the inquiry from Dr. Jean Henderson and the answer regarding hazards of exposure to "glass wool" or "fiber glass," published in *Queries and Minor Notes* in *THE JOURNAL*, May 1, page 69.

The first fibrous glass made in the United States on a commercial scale was produced in my own state in 1934, in what are now the Newark, Ohio, factories of Owens-Corning Fiberglas Corporation. Since 1934 fibrous glass in the wool-like form commonly called glass wool has been produced continuously in these factories.

As chairman of the Committee on Industrial Health of the Ohio State Medical Association and as medical consultant for Owens-Corning Fiberglas Corporation, I have considerable personal knowledge of the health aspects of the manufacture of fibrous glass and of investigations in this field by independent medical authorities.

I do not have similar knowledge of the manufacture of foam glass or of the production of glass frit, but I do know that the processes are quite unrelated to those used in the manufacture of glass fibers or glass floss—the subject of Dr. Henderson's inquiry. Although the material sold as glass floss is not manufactured by the Fiberglas Corporation, the reply to Dr. Henderson embraces the whole range of products made of glass fibers and therefore comes within the scope of my experience.

This knowledge leads me to believe that that part of the answer which pertains to the health hazards of glass wool may be misleading to readers. In an effort to clear up any misconceptions which the answer may have been responsible for, I should like to review and comment on certain of the statements made in it.

The answer correctly states that the process of manufacture of glass fibers differs with the ultimate use contemplated for the fibers, but the description of the process employed in the manufacture of fibers for the wool-like form of fibrous glass is correct only for one type of glass textile fibers and is completely incorrect for fibers fabricated into the wool-like form—the material to which both question and answer refer.

This is unimportant, but the answer then lists the following as specific exposures: (1) the usual ill effects of high temperatures; (2) mechanical injuries from spicules of glass; (3) carbon tetrachloride or ether vapors, which chemicals are sometimes used to remove a mineral oil lubricant, at times applied to the glass fibers to promote disentanglement.

Exposure to high temperatures is common in a great number of manufacturing processes. In many industries it is almost as much a concomitant of factory work as is exposure to the heat of the sun a concomitant of the farmer's labor. Such exposure can become a hazard only under exceptional circumstances. No such exceptional circumstances are present in the manufacture of fibrous glass, and I have never before heard it suggested that exposure to high temperatures constitutes a hazard for such workers.

From time to time newly employed workers, unaccustomed to handling fibrous glass, have experienced a short period of discomfort due to a nondisabling and superficial mechanical irritation of the skin caused by spicules of glass. Such discomfort has usually lasted only a few days, passing as soon as the worker became used to handling the material.

During the spring and summer of 1942 Dr. Marion B. Sulzberger, assistant clinical professor of dermatology and syphilology,

New York Post-Graduate Medical School, and Dr. Rudolf L. Baer, junior assistant dermatologist and syphilologist, New York Post-Graduate Hospital, carried out an experimental investigation of the effects of fibrous glass on the skin of laboratory animals and human volunteers.

Summarizing the results of the investigation, Dr. Sulzberger and Dr. Baer say:

All of the reactions observed were of a transitory and superficial nature. The only part of the reactions which persisted for more than a few days were slight thickening and brownish pigmentation of the skin. The latter were sometimes apparent for several weeks. No reactions or symptoms outside the rubbed skin areas were observed at any time during the experiment.

The pieces of material which were seen sticking into the skin after rubbing with Fiberglas in its wool-like form appeared to be very superficially embedded. This observation was borne out by the fact that ordinary washing with water easily removed a large part of the spicules remaining in the skin after rubbing.

A full report of the Sulzberger-Baer investigation was published in *Industrial Medicine* (11:482 [Oct.] 1942).

Neither carbon tetrachloride nor ether vapors are used for any purpose at any stage in the manufacture of fibrous glass in any of its forms. The manufacturers of fibrous glass supply other manufacturers with various fibrous glass products for incorporation in products which these manufacturers produce. For some highly specialized applications some of these other manufacturers may wish to remove the lubricant that is applied to glass fibers during the manufacturing process to prevent them from abrading one another, not, as *THE JOURNAL* answer states, "to promote disentanglement." Removal of the lubricant is rarely required.

Carbon tetrachloride or ether vapors are among the solvents that may be used to remove the lubricant from the fibers. Their employment, however, has no more connection with the manufacture of glass fibers and fibrous glass products than has the removal of paint from a chair to do with the manufacture of the chair.

THE JOURNAL answer states that it is doubtful whether any specific pneumoconiosis is likely to arise from working with glass wool. That no such pneumoconiosis can arise is indicated by the following statement by Dr. Leroy U. Gardner, director of the Edward L. Trudeau Foundation for Research and Teaching in Tuberculosis:

Exposure to the dust of glass wool, a material commonly used to insulate buildings, involves no hazard for the lungs because this fibrous material is not inhalable.

This statement by Dr. Gardner appeared in the 1941 report of the director of the Trudeau Foundation and followed an investigation of the effects of exposure to glass wool dust conducted by Dr. Gardner over a period of several years.

Finally, I should like to point out that no claim for workers' compensation based on a pulmonary industrial disease, or disability resulting from an occupational skin disorder attributable to fibrous glass as differentiated from other materials, has ever been validated in the state of Ohio, where manufacture has been centered since 1934.

INTENSIVE TREATMENT OF SYPHILIS

To the Editor:—I have recently observed a case of clinical and serologic relapse occurring within one month after the patient had been given the five day treatment for syphilis under the direction of an officer of the United States Public Health Service. I have been informed of a probable neurorelapse following the administration of penicillin in a case of early syphilis. I am reminded also of the epidemic of early neurosyphilis which occurred in Europe almost immediately following the introduction of arsphenamine.

When we consider the action of some of our newer chemical compounds, including penicillin, which are used in the treatment of early syphilis and some of which, like penicillin, gain access slightly if at all to the cerebrospinal fluid, we should keep in mind the early experience with arsenicals. Every effort should also be made to guard against those previous disastrous results, particularly in view of the fact that, had we known then what we know now, most of the hundreds of cases which occurred in 1910-1912 could easily have been prevented. (For references see the several books on arsphenamine edited by Ehrlich as well as numerous articles on the neurorecidiv which appeared in European medical journals of that period. Also the collection of 212 cases published by Bernario in 1911 in the book *Ueber Neurorecidiv*. Not all of the cases collected by Bernario followed the administration of arsphenamine.)

Many will recall the heated discussion which took place between the Vienna school headed by Professor Finger and the Berlin group led by Professor Ehrlich concerning this matter. The question was definitely settled in 1913. Without entering into a lengthy discussion of the facts which settled the dispute, since that would lead to detailed consideration of *Treponema pallidum*, as well as the question of immunity in syphilis and the adequate treatment of the disease, suffice it to say that the cause of the appearance of so many cases of early neurorelapse was the inadequacy of the treatment of the infection and not the direct action of the arsenical, as Professor Finger first maintained.

The crux of the matter is that, if early syphilis is to be treated efficiently, it should be treated not only with a view to arresting its infectiousness, which obviously is of major importance, but also with a view to the protection of the future of the individual per se.

Our newer remedies offer the prospect that the infectiousness can be checked promptly, but they do not offer a certain pros-

pect that complete sterilization can be produced. Indeed, it appears from the properties and actions of some of these chemical agents quite probable that they will not completely sterilize, when we consider the pathogenesis of the disease process and the fact that these drugs, by rapidly destroying many of the organisms, do by this action materially lower a very essential factor in cure—the patient's immunity.

The general practitioner, who must of necessity treat the disease, and the syphilologist, who treats a limited number of cases, should proceed cautiously in adopting any of the newer methods until the larger facilities have more definitely determined the real worth of these methods. Although it will take some time before this can be settled, combined chemotherapy and fever may be at least one of the means of effecting an early biologic cure. The former, although powerfully treponemocidal, indirectly suppresses immunity, while the latter enhances it.

Let us not make the identical mistake which Professor Ehrlich made in the early part of the arsphenamine period. It will be forever to his credit, however, that he was the first to recognize this mistake and to correct it. In other words, if we are to use any of the various "rapid cures," let us strive actually to cure by as safe a procedure as possible and by a close and careful follow-up, if we use a method that we know retards or prevents the patient's immunity. Already too many patients have been sacrificed.

It is not probable that a great number of cases will appear, since most of the new methods are more efficient than a dose or two of arsphenamine, which was largely responsible for the early outbreak. As we now know the cause and the prevention, we are equipped to forestall a recurrence of a disastrous episode.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Dental Practice Acts: Validity of Board's Rules Respecting Advertising.—The Michigan state board of dentistry adopted six rules, in the main prohibiting the splitting of fees and regulating advertising by licensed dentists. Several licensed dentists, including the plaintiff, Toole, filed suit to prevent the board from enforcing those rules, alleging that the rules were null and void because they either exceeded the power granted the board by the dental practice act or, if authorized by the act, were the result of an unlawful delegation of legislative power to the board. The Michigan state dental society intervened in the action. The trial court dismissed the suit, and the plaintiffs appealed to the Supreme Court of Michigan.

In testing the right of the board to adopt the rules in question, said the Supreme Court, it must be borne in mind that the Michigan dental practice act puts the practice of dentistry under the supervision of the board and gives it the power to "adopt rules and regulations for its own organization and for the practice of dentistry . . . and for carrying out the provisions of this act." We must also be guided by our previous decisions germane to the construction of the act in this regard. For instance, in *Argo Oil Corporation v. Atwood*, 274 Mich. 47, 264 N. W. 285, we said:

It is too well settled to need the citation of supporting authorities that the Legislature, within limits defined in the law, may confer authority on an administrative officer or board to make rules as to details, to find facts, and to exercise some discretion, in the administration of a statute.

Again, in *Sullivan v. Michigan State Board of Dentistry*, 268 Mich. 427, 256 N. W. 471, we said:

It is not to be presumed that the board will adopt any rules and regulations for the practice of dentistry that do not meet the test of constitutionality.

We must also remember, as was said in *Johnston v. Board of Dental Examiners*, 77 U. S. App. D. C. 119, 134 F. (2d) 9, that

The regulations of the Board are valid so long as they are not unreasonable or arbitrary. If any doubt exists as to their invalidity, they must be upheld.

The first rule adopted by the board in effect prohibited any person from splitting or dividing with any other dentist or layman any fees earned in rendering any dental service, provided that the rules should not be interpreted to prevent an employer from paying an employee. The plaintiffs claimed that the enforcement of this rule would prevent partnerships in the practice of dentistry. It is to be noted, said the Supreme Court, that the dental practice act prevents the practice of dentistry by corporations, but nowhere in the act do we find such practice by partners prohibited, nor do we interpret the first rule as preventing such practice by partners. The rule was aimed at the splitting of fees between dentists or between a dentist and a layman. We do not find the rule running counter to the purposes of the framers of the legislation.

The second rule adopted by the board of dentistry prohibited a dentist from using a sign employing a background of more than 300 square inches or using letters thereon of a size greater than 5 inches. Section 17 of the dental practice act, said the court, makes it unlawful to advertise by means of large display signs, or glaring light signs, electric or neon, or such signs containing as part thereof the representation of a tooth, teeth, bridgework, plates of teeth or any portion of the human head, or to use specimens of such in display, directing the attention of the public to any such person or persons engaged in the practice of dentistry. In *Modern System Dentists v. State Board of Dental Examiners*, 216 Wis. 190, 256 N. W. 922, it was held that a rule prescribing a maximum of 600 square inches for a dentist's sign outside his office building and the maximum size of letters thereon was within the authority of the state board. In our opinion a rule that permits a maximum of 300 square inches is a matter that lies in the sound discretion of the rule making body and is within the power granted by the statute.

The third rule adopted by the board prohibited the use of more than one outside sign. We are in accord, said the Supreme Court, with the reasoning of the trial court in upholding this rule:

Several signs placed in juxtaposition to one another would constitute one large sign, and the regulation dealing with size would be a nullity if it permitted the dentist to accomplish through multiplicity of signs the effect which is denied through a single sign.

The fourth rule adopted by the board prohibited a dentist from using illumination on a sign other than that of the indirect type or of a type lighted from within and limited the illumination to no greater intensity than that provided by 100 watts of incandescent lighting or its equivalent, provided further that no colored illumination should be used nor any exposed luminous tube, nor any flasher, nor any intermittent mechanism be employed, provided also that no signs should be illuminated except during the time that the dentist or his associates are actually in the dental office and prepared to render service. It is evident, said the court, that this rule is intended to prevent all-night illumination. We are not in accord with the claim of the plaintiffs that this rule prevents a dentist from leaving the sign operating if he temporarily leaves his office. The legislature has provided that a dentist may not advertise by "glaring light signs, electric or neon." The rule as adopted by the board is in harmony with the intent and purpose of the dental practice act.

The fifth rule adopted by the board prohibited the practice of any dentist in an office where it is indicated, by sign or otherwise, that some one else owns or operates the office, with the sole exception that if a dentist has died his practice may be carried on for a period of six months under his name. The purpose of this rule, said the court, is not only to prohibit the practice of dentistry by any person whose name is not displayed on the office door or window but also to assure the public that the person whose name is so displayed is a practicing dentist in that particular location. The dental practice act provides specifically that it shall be unlawful to "make use of any advertising statements of a character tending to mislead or deceive the public." It is evident that this rule was adopted to carry out this provision of the act. In our opinion, the rule conforms to the intent and purpose of this portion of the dental practice act.

The sixth rule promulgated by the board regulated the size of professional card announcements, restricting the size of professional card announcements in newspapers or other similar circulating mediums to a space equivalent to a 2 inch column in width and 1 inch in length, with certain restrictions on the size and style of type used. The dental practice act, said the court, provides that dentists may make certain newspaper announcements. In our opinion, the sixth rule is a sound interpretation of that which the act permits and, as such, is not contrary to the necessary implications of the dental practice act. In our opinion, it was the intent of the legislature to establish the primary standard for the rule making body to follow and that the board in adopting the sixth rule has merely carried out the details in the administration of the dental practice act.

The court could find no sound basis for disturbing the rules adopted by the state board of dentistry and accordingly affirmed the decree of the trial court dismissing the action.—*Toole v. Michigan State Board of Dentistry (Michigan State Dental Soc., Intervener)*, 11 N. W. (2d) 229 (Mich., 1945).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Effects of Lead Poisoning in Mental Development.—

According to Byers and Lord it has not been generally recognized that lead poisoning occurring in early life usually has a disastrous effect on mental development. They present a follow-up study of 20 school children who had been hospitalized in infancy or early childhood because of lead poisoning. None of them exhibited striking evidence of encephalopathy during their primary admission, and all were adjudged to have made a complete recovery from lead poisoning when discharged from the original hospitalization. The authors emphasize the length of the cycle of ingestion, storage and elimination of lead in relation to the relatively short duration of the symptoms and signs allowing a diagnosis of lead poisoning. It seems probable that lead poisoning of the sort here discussed can at present be recognized in only a small percentage of cases. Failure of the normal processes of growth and development of the cortex prevented all but 1 of the 20 children from progressing satisfactorily at school. In addition to difficulties in the general intellectual and sensorimotor spheres, other evidence of interference with the normal development of the nervous system were found. Recurrent convulsions appeared in 3 of the children, at 4, 4½ and 5½ years of age. One girl who had peripheral neuritis as a baby acquired a positive Babinski sign, and 1 boy who was discharged from the hospital as well at about 3 years of age had hyperactive reflexes and sustained clonus at the left ankle when reexamined at 9 years. Behavior difficulties were common throughout the series. Much of this behavior could be classified as "forced reaction to stimuli in the environment" described by Strauss and Werner as an evidence of cortical damage. It was apparently the result of loss of the normal inhibitory function, thought to reside in the cortex. It was usually described as unreliable impulsive behavior, cruel impulsive behavior, short attention span and the like.

Radioactive Iodine Studies in Childhood Hypothyroidism.—Hamilton and his associates stress the usefulness of radioactive isotopes of iodine in the study of iodine metabolism, pointing out that they are of particular value in measuring the gross iodine metabolism of the thyroid *in situ*. The radioactivity of a single dose of radioiodine enables one to follow its metabolic fate. The radioiodine concentrated in the thyroid may be determined quantitatively without surgical removal of the gland, since the gamma rays emitted by it penetrate the overlying tissues and can be measured with a suitable detecting device, such as the Geiger-Müller counter. Thus, the addition of a trace of radioiodine to ordinary iodine serves to label all the iodine atoms in an administered sample. The 10 children included in these studies had severe hypothyroidism. It was observed that the thyroids of children with hypothyroidism and without goiters are able to concentrate only small amounts of

orally administered iodine, as compared with the thyroids of normal children or adults. In these hypothyroid children the remaining thyroid tissue concentrated a larger percentage of a dose of 0.1 microgram than of a dose of 14 mg. of iodine. The thyroids of 2 children with goiters and with severe hypothyroidism took up relatively large amounts of iodine and by chemical analysis contained both thyroxine and diiodotyrosine in considerable quantities. The uptake curves of the thyroids as measured *in situ* were similar to those seen in hyperthyroidism in adults. Radioautographs made from sections of the thyroids of both of these children indicate that by the fifth day after the oral administration more of the iodine was in the cells than in the colloid.

Penetration of Sulfonamides into Skin.—Strakosch and Clark performed *in vivo* experiments on guinea pigs and human beings to determine the penetration of sulfonamides from various vehicles into the skin. Skin biopsies were analyzed for total sulfonamide concentration after varying times of application. Sulfanilamide, sulfathiazole and sulfadiazine, in a comparable base at comparable concentrations and times of application, gave comparable tissue levels, demonstrating no difference in penetration into intact skin. Sodium sulfacetimide ("Albucid soluble"), on the other hand, gave greater penetration after a three day application time than the sulfonamide bases tested. Increasing the concentration did not increase the absorption by the intact skin of sulfanilamide, sulfathiazole and sulfadiazine. Even sodium sulfacetimide showed only a slight effect of concentration. Increasing the time of application increased the skin absorption of sulfonamide in all cases, especially of sodium sulfacetimide. Of seven ointment bases examined, two oil in water and five water in oil emulsions, the type of emulsion had no effect on the absorption of sulfonamide by the skin, including the sodium sulfacetimide. One water in oil emulsion was superior to the others tested. An ointment containing a solubilizer and a wetting agent in greater amounts than in the other bases studied did not give better absorption of sulfathiazole by the skin than the other bases. Injured skin absorbs much greater amounts of sulfonamides from ointments than intact skin. Sodium sulfacetimide is especially penetrating into injured skin. Injured skin absorbs sulfonamides from wet packs to a much greater extent than from ointments.

Toxicity of Penicillin.—Hamre and her associates in the course of experiments on gas gangrene observed that 7 guinea pigs which had been infected with *Clostridium perfringens* and treated subcutaneously with penicillin died, although they had shown no symptoms of gas gangrene. They had received from 2,600 to 4,000 Florey units per kilogram daily in seven doses daily for three to four days. The amounts of penicillin given to these animals were well below the toxic level for other animals, but the possibility remained that guinea pigs are

more susceptible to penicillin than other animals. To investigate this possibility, further experiments were undertaken. It was found that from 7,000 to 12,000 Florey units per kilogram daily of penicillin, as prepared for clinical use, given subcutaneously over a period of several days caused death of guinea pigs but not of mice or rabbits. However, a dose approximately that used clinically (1,000 Florey units per kilogram) given subcutaneously for twenty days did not kill guinea pigs. All animals given penicillin subcutaneously showed a severe reaction at the site of injection. Seven samples of penicillin prepared by different methods in two different places were toxic when given subcutaneously to guinea pigs for several days. Large doses of sodium ascorbate did not protect guinea pigs from the toxicity of repeated subcutaneous doses of penicillin.

Vitamin A Concentrate in Normal and Hypertensive Patients.—According to Taylor and his collaborators substances containing vitamin A, such as the nonsaponifiable fraction of butter, have been shown to increase urea and inulin clearances in normal dogs and in dogs deprived of dietary vitamin A, to increase the rate of glomerular filtration. Similarly, large doses of concentrates of the vitamin increased urea clearance in human beings. Although the increase in inulin clearance specifies the change as one associated with increased rate of glomerular filtration the mechanism of its increase remained unknown, and it is part of the purpose of this study to determine its nature. The authors also examined the effect of large doses of vitamin A concentrate in essential hypertension, since Govea, Peña and Villaverde recommended the use of the vitamin in this disease. The authors found that the administration of a preparation of vitamin A in amounts ranging from 100,000 to 400,000 units daily for from five to ninety days in 3 normotensive and 14 hypertensive patients did not alter the levels of arterial pressure. Observations of renal function in 2 normotensive and 11 hypertensive patients revealed increased effective renal blood flow in 9, increased glomerular filtration rate in 7 and increased tubular secretory capacity for diodrast in 4 of 7 hypertensive patients in whom this function was tested. The increase in effective renal blood flow was usually associated with increased cardiac output, the result of tachycardia and not of increased stroke volume. On the basis of these observations the authors arrive at the following conclusions: 1. Vitamin A concentrate is ineffective in the treatment of essential hypertension in doses of 100,000 to 400,000 units daily for from five to ninety days. 2. The vitamin concentrate causes renal vasodilatation and increased functional capacity for secretion of diodrast with increased cardiac output. The suggestion is made that it may have application in the treatment of degenerative renal diseases.

Ascorbic Acid in Tuberculous Navajo Indians. M. Pijoan and B. Sedlacek, with assistance by C. A. Elkin and R. L. Warren.—p. 342.

Significance of Rare Bacilli in Sputum.—The Pottengers submitted specimens of sputum from each patient to examination at intervals of from four to six weeks while under treatment and from many patients at longer intervals after discharge—in some cases for nearly fifteen years. A sterilized bottle is provided, and the patient is required to save everything expectorated. The patient is not trusted to separate lung from throat sputum. Three day specimens are required and, if the first one is negative, four or five additional specimens are collected. The sputum is examined by the dilution-flotation picric acid method and, when guinea pig inoculation is used, two thirds of the homogenized specimen or its concentrate is injected. Specimens are searched for a minimum of ten minutes (a total of about 200 microscopic fields) before they are declared negative. The authors think that acceptance of the Ziehl-Neelsen method as sufficient for determining the presence of tubercle bacilli is a cause of much inaccuracy both in diagnosis and in estimating the results of treatment; for this may show grossly positive sputum as negative. Case reports show that occasional bacilli may persist for a long time. The authors' experience indicates that, if the patient is clinically well, there is little danger from rare bacilli found by very sensitive methods, either to himself or to those with whom he associates. Sometimes larger numbers of bacilli will be temporarily discharged by one who has been clinically well, the patient returning at once to the rare or negative stage without reactivation of his disease. The persistence of bacilli occurs whether the patient has been treated by physiologic methods alone or by collapse procedures. The presence of occasional bacilli in sputum does not necessarily mean that the patient is suffering from clinically active tuberculosis, but it shows that active tuberculosis has been present. This finding may be consistent with good health and full working capacity. Patients with occasional bacilli are probably of greater danger to themselves than to those with whom they associate, because bacilli are present in the tissues and may produce endogenous spread in case the proper stimulus is present. As regards the danger to others, it would probably be greater to children than to adults, and to the less resistant than to the stronger. The presence of occasional bacilli in the sputum, as determined by exacting technics, is in the same relationship to diagnosis and cure as is the tuberculin test. It gives evidence of only limited value. The true estimate must depend on clinical judgment.

Pneumoperitoneum in Pulmonary Tuberculosis.—According to Rudman the reports on the efficacy of pneumoperitoneum in pulmonary tuberculosis ran the whole gamut of enthusiasm to pessimism. The advocates of pneumoperitoneum claim that the beneficial results brought about are due to (1) elevation of both hemidiaphragms giving rest to the diseased lung, (2) lymph stasis, which in turn promotes tissue fibrosis, and (3) pulmonary congestion and anoxemia, which in turn inhibit the growth of tubercle bacilli in the tissues and hasten reparative processes. The author shows, however, that these theoretical considerations do not always work out in practice: the mobility of the diaphragm may be impaired, subdiaphragmatic adhesions may limit the rise of the diaphragm, and the intra-abdominal pressure may cause a downward displacement of the abdominal viscera. But while in the advanced cases the presence of subdiaphragmatic adhesions, the extent of the lesions in the lung tissue and tonus of the diaphragm may nullify whatever benefits there are to be obtained from pneumoperitoneum, far better results are brought about when pneumo-

peritoneum is used in the early or moderately advanced case to enhance the value of phrenic neurectomy. Pneumoperitoneum is a far more formidable procedure than pneumothorax and therefore should be done with great caution and care. The author briefly describes the technic and then presents several case histories, in some of which pneumoperitoneum gave disappointing results. He summarizes the indications for pneumoperitoneum in pulmonary tuberculosis as follows: 1. It is indicated as a trial measure to determine diaphragmatic mobility and freedom from interfering subdiaphragmatic adhesions prior to phrenic interruption. 2. In cases in which a breakdown and reactivation of the tuberculous process have occurred after an effective phrenic operation, it may be possible by means of pneumoperitoneum to prevent reopening of the cavity. 3. Its greatest value lies in its ability to enhance the value of the diaphragmatic rise following phrenic interruption. 4. It is of value in preparing the patient for radical surgery and in making the lesion quiescent in less time than could be accomplished by bed rest alone. Pneumoperitoneum is of limited value as the sole therapeutic measure in pulmonary tuberculosis. Its benefits are not lasting.

New Resuscitation Apparatus.—The apparatus described by Kreiselman consists of an expansible bellows type bag of about 1,600 cc. capacity, a face mask and a valve placed between them. There are valves for the intake of air and oxygen and a safety valve which limits pressure to 20 mm. of mercury. The apparatus operates to inflate the lungs with either air or oxygen at a safe, controllable predetermined pressure. Normal respiratory exchange with atmospheric air can take place while the apparatus is applied. When breathing begins the patient is always in free communication with either atmospheric air or the gases in the bag. Gases from the lungs cannot mix with the gases in the bag. The apparatus operates equally efficiently in any position. The apparatus when used in conjunction with the prone pressure method of artificial respiration greatly increases the effectiveness of that method. The apparatus meets the mechanical requirements for satisfactory and safe resuscitation, using a simple technic, and is small, light, compact, inexpensive and mechanically simple.

Sulfonamides in Damage of Liver.—Peterson and his associates studied the effects of the administration of sulfonamide compounds on the clinical course and hepatic function of 37 patients with various disorders of the liver. All patients studied were admitted to Boston City Hospital. Only those are considered in whom there was clinical and laboratory evidence of damage to the liver and in whom tests of hepatic function were made before and after a course of some sulfonamide compound. Thirteen of the patients had acute hepatitis. In all except 1 of these patients, who had a catarrhal jaundice,

the damage to the liver, was secondary to an acute pyogenic infection. The remaining patients had chronic disease of the liver and included 14 with portal cirrhosis, 5 with biliary cirrhosis, 4 with damage to the liver resulting from chronic congestive cardiac failure and 1 with diffuse carcinomatosis. To most of the patients the sulfonamide compound was given in the usual therapeutic doses and for a definite pyogenic infection. To a few, however, the drug was given because of a suspected infection, the presence of which was not substantiated. Sulfathiazole and sulfadiazine were each used alone for 14 patients; both were given in succession or on separate occasions to 7, and 2 received sulfapyridine. The authors found that in the patients with acute hepatitis associated with bacterial infections the sulfonamide therapy was almost invariably associated with improvement in hepatic function which paralleled the improvement in the underlying infection. In the patients with chronic damage to the liver, hepatic dysfunction was not aggravated by administration of sulfathiazole or sulfadiazine. There was some improvement noted as a result of such therapy in cases in which bacterial infection was adding to the hepatic injury. Severe toxic effects of sulfonamide therapy other than direct injury to the liver were unusually frequent in the patients with portal cirrhosis and were twice as common after sulfathiazole as after sulfadiazine. The authors conclude that the presence of damage to the liver should not be considered a contraindication to therapy with sulfathiazole or sulfadiazine in patients with bacterial infections against which these drugs are effective. Sulfadiazine is the drug of choice in such cases. Caution should be exercised in the administration of sulfonamide compounds to patients with severe portal (Laënnec's) cirrhosis of the liver.

Anaphylaxis After Injection of Tetanus Toxoid.—After citing statistical figures on the incidence of severe reactions following immunizations with precipitated toxoid, Edwards reports the history of a man aged 29 who developed an anaphylactoid type of reaction after the administration of tetanus toxoid. The development of edema of the eyes and lips followed by collapse after a third injection of plain tetanus toxoid is obviously an anaphylactoid type of reaction. This is substantiated by skin tests and passive transfer studies to human skin. Allergy studies point to the veal infusion contained in the toxoid as the responsible factor. It is interesting that the patient gave no history of asthma or hay fever, and his skin tests with diagnostic allergens were all negative. This demonstrates that severe reactions do occur in the absence of a history of allergy. Cooke and his associates pointed out that all persons receiving tetanus toxoid should first be given skin tests. Gold discourages skin tests, but the apparent indifference of Gold to positive skin tests is certainly not shared by all. Edwards observed the sudden death of a young person who had not been given previous sensitivity tests twenty minutes after the injection of a second dose of plain tetanus toxoid combined with a third dose of typhoid vaccine. Autopsy revealed the presence of pulmonary edema. To minimize the significance of a positive skin test and then unhesitatingly administer the full dose parenterally is definitely contrary to the orthodox practice.

Experimental Trinitrotoluene Poisoning.—Smith and his associates point out that one chemical change which uniformly has been found in experimental trinitrotoluene poisoning is the formation of a variable amount of diazotizable material in the tissues and body fluids, indicating the formation of reduced degradation products. It has been suggested that at least some of the reduced compounds may be detoxified by conjugation with glucuronic acid. If this is an essential mechanism of detoxification, ascorbic acid might play an important part, since it has been shown that it can detoxify phenol in a manner analogous to glucuronic acid. Experiments were undertaken to ascertain the effects of ascorbic acid in chronic trinitrotoluene poisoning in several animal species; animals highly susceptible to trinitrotoluene, as the cat, and animals with a high natural resistance to it. In the latter group rats were used, which do not require exogenous ascorbic acid, guinea pigs, in which exogenous ascorbic acid is indispensable, and rabbits, which are intermediate in this respect. It was found that the administration of ascorbic acid had little effect on the course of chronic trinitrotoluene poisoning in rats, guinea pigs or rabbits. In cats, which are relatively highly susceptible to trinitrotoluene poisoning, ascorbic acid appeared to have a slightly favorable influence on the course of intoxication. The distribution and elimination of reduced degradation products of trinitrotoluene

were not materially influenced by the ascorbic acid treatment. The glucuronic acid output in the urine was not influenced by trinitrotoluene, and the somewhat augmented output in porphyrins noted in some animals was not affected by ascorbic acid treatment.

Oxygen in Electroshock Therapy.—Holovachka reviews observations on 178 electroshock treatments without and on 125 with oxygen. A mask of nasal type was held over the nose the instant the current was sent into the electrodes. The oxygen was maintained at 8 liters per minute until cyanosis completely disappeared, a time which seldom exceeded four minutes. The total amount of oxygen consumed averaged 40 liters and was supplied from a large industrial cylinder. The question of increased effectiveness of the treatment with oxygen cannot be answered, because the number of cases are not adequate. However, the tolerance for treatments was increased so that the hazard to patients with cardiac dysfunction was diminished. One hundred and seventy-eight treatments without oxygen resulted in 54 complaints of headaches, 5 instances of remarkably persistent cyanosis, 75 confusional states, which were observed as late as six hours following a morning treatment, and 14 episodes of nausea and vomiting. These were contrasted with 125 treatments in which oxygen had been administered, resulting in 15 complaints of headache, no pronounced cyanosis, 1 confusional state and 1 case of nausea and vomiting.

White Bile.—According to Schwyzer, "white bile" is a misnomer. It is often not white but a colorless liquid like water, and it is not bile. However, it is in the place where normally bile is found. Hydrops of the gallbladder is not considered in this report. The author's experience with white bile is limited to 9 cases. In 2 of them normal bile appeared on the evening of the day of operation, in another after twenty-four hours and in the fourth one after thirty-six hours. They recovered. A fifth one died of cholemia after barely four days without return of normal bile, not even the slightest coloring. The other 4 cases are described in detail. In 1 case a chemical analysis of the white bile was made. It was found to contain neither bile acids nor bile pigment nor digestive ferments. What looked like white bile in another case was due to reflux of pancreatic secretion through a catheter in the common bile duct. The author stresses that the white bile as seen by the pathologist in sepsis rests on a fundamentally different cause from that seen by the surgeon in cases of obstruction of the bile ducts. Infection is not the basic cause in the surgical white bile. The underlying condition is obstruction to the bile flow, though frequently infection also is present. White or, rather, colorless bile is a secretion of the ducts with their glands. A water colored secretion from bile choked liver acini is not really thinkable. On the other hand, a poorly colored or even uncolored bile in overwhelming sepsis without noticeable obstruction is the result of greatly disintegrated liver, though even here some obstructive swelling may cooperate. Dextro-galactose tests indicate that, in cases of even severe icterus experimentally provoked by ligation of the common duct, the liver function is not (at least for a long time) destroyed in this respect. Normally colored bile may start flowing immediately after decompression followed by recovery or may not appear until death. If normal bile does not appear thirty-six or forty-eight hours after releasing of the obstruction the prognosis becomes grave, though even after four days' delay recovery was observed.

Abnormal Uterine Bleeding in Adolescence.—Winther found that, of 7,634 women entering the University of Minnesota from 1938 to 1942, 22 per cent complained of irregular menstruation. During these four years 2,302 students have consulted the gynecologic department of the Student Health Service, 630 of whom came because of irregular bleeding. Treatment must be preceded by a careful examination to determine the cause of the abnormal bleeding. In the adolescent, abnormal bleeding is frequently self limited and is best left untreated. Endocrine therapy should be used cautiously. Desiccated thyroid is indicated when the serum cholesterol concentration is increased or the basal metabolic rate is decreased. Excellent results have been obtained in profuse menstrual bleeding with small doses of thyroid. An endometrial biopsy or hormone

assays should precede the use of estrogens. They should not be given to the adolescent in large doses over a long period of time because they do not stimulate the growth of the ovaries but actually inhibit the pituitary and thus reduce the ovarian function. Progesterone also has been used in the treatment of abnormal uterine bleeding. Chorionic gonadotropin has given good results in profuse uterine bleeding in the adolescent. The dosage is difficult to calculate. Sixty-four patients with profuse menstrual bleeding were treated at the University Health Service from 1938 to 1942. Forty-six were given chorionic gonadotropin. Thirty-eight responded favorably. Equine gonadotropin (gonadogen) was given to 17 with improvement in 40 per cent of the cases. It is better not to give testosterone unless one understands its limitations and dangers. Combined treatment with estrogens and progesterone have been used successfully in amenorrhea and profuse bleeding. The immediate control of severe bleeding is the real problem. Rest in bed and oxytocics may control the hemorrhage. Posterior pituitary injection or ergonovine may be used as a temporary control. A curettage should be performed if the bleeding continues. Blood transfusions should be given in cases of severe anemia. Good results have been reported from using pregnant donors or lactating women. In the 2 cases in which moccasin snake venom was used by the author it did not affect the bleeding. Vitamin K may be given. General health measures are important in preventing recurrences of abnormal bleeding. Low dosage irradiation of the pituitary or ovary in the adolescent must be used with great caution.

Rh Substance in Transfusion Reactions.—Koucky presents the nature of the reactions due to Rh sensitization and discusses the Rh substance, the Rh antibody and other aspects of this problem, citing 16 illustrating case reports. He stresses that the Rh substance is similar to the A and B substances which determine the division into the four blood groups. Rh positive individuals cannot become sensitized. Rh negative individuals, if inoculated by transfusion—or during pregnancy from the fetus—may develop antibodies. The Rh substance varies in its antigenic property: some persons become sensitized very readily, while others do not. The antibody which can be demonstrated in the laboratory is the agglutinin. Apparently other types of antibodies are formed which are not detected by laboratory tests but will produce transfusion reactions or erythroblastosis in the fetus. The absence of demonstrable agglutinins, therefore, does not exclude the presence of dangerous antibodies. In pregnancy the antibodies may develop between the eighth and twelfth weeks, so that transfusions after early abortions must be handled as those later in pregnancy. An investigation of the obstetric history of women should be made prior to a transfusion and, if evidence of erythroblastosis in the babies is present, the possibility of sensitization should not be overlooked. Except under rare circumstances whole blood should never be given to pregnant or puerperal women until their Rh grouping is known. If multiple transfusions are to be given, a knowledge of the Rh grouping is very helpful. If Rh positive, the transfusion program can be carried out with no worry relative to Rh sensitization. If the patient happens to be Rh negative, an attempt may be made to complete the transfusion program within the five or six day period before antibodies can develop. After reactions develop, the transfusion program can be continued but only by using Rh negative donors. In transfusing erythroblastotic babies, the mother's blood should not be used.

Succinylsulfathiazole and Phthalylsulfathiazole as Intestinal Antiseptics.—According to Poth, sulfanilylguanidine, which has been used successfully in the treatment of bacillary dysentery, has little antibacterial activity when there are ulcerations in the bowel. This may explain the ineffectiveness of sulfanilylguanidine late in the disease. Succinylsulfathiazole alters the bacterial flora and reduces the bulk of the fecal material while rendering it semifluid. For this reason it can be used in the preoperative treatment of the gastrointestinal tract. Succinylsulfathiazole 0.25 Gm. per kilogram of body weight, divided into six equal portions, is administered at four hour intervals by mouth. Postoperatively no gastric suction is used, and as soon as the patients can take 30 cc. of warm water, and this usually occurs within twenty-four hours after operation, the administration of the drug, similar to the preoperative regimen, is reinstituted. The drug is tolerated surprisingly well. Its administration is continued for from twelve to fourteen days postoperatively. In a series of some 50 patients in whom primary sutures of the large bowel was undertaken there has been no instance of peritonitis or fecal fistula. The studies on acylated sulfonamides as intestinal antiseptics have been extended to new compounds, including phthalylsulfathiazole (sulfathalidine). This compound showed from two to four times the bacteriostatic activity of succinylsulfathiazole locally in the gastrointestinal tract, as indicated by the alteration of the coliform flora. Phthalylsulfathiazole, like succinylsulfathiazole, is sparingly absorbed from the gastrointestinal tract and should be more effective in treating bacillary dysentery than is succinylsulfathiazole or any other of the known sulfonamides.

Thiourea in Treatment of Thyrotoxicosis.—Himsworth confirms Astwood's claims for the initial effects of thiourea in cases of thyrotoxicosis. Six cases have been treated. The author gives a detailed description of 1 severe case. The results in the other, milder cases were similar but less dramatic. In 1 case thyroidectomy was done because the goiter was compressing the trachea. In this case thiourea alone was given and proved a satisfactory preoperative preparation. The tissue removed at operation was hyperplastic and practically free from colloid. Two disadvantages have been found, and these have proved trivial. Thiourea has a nauseating taste, and at the beginning of therapy considerable nausea or even vomiting may occur. The second disadvantage is the peculiar sweet smell which it imparts to the breath. Discussing the mode of action of thiourea, the author says that the evidence at present available indicates that thiourea acts by interfering with the synthesis of the thyroid hormone.

Sternal Puncture in Diagnosis of Malaria.—According to Aitken, examination of the sternal bone marrow may help in diagnosis of malaria. He reviews a series of 105 cases to draw attention to the value and limitations of this method. To compare the aspects of marrow with those of the blood, sternal puncture was performed on 10 patients with parasites in the peripheral blood. The marrow fluid in each case contained a substantially higher proportion of cells containing parasites. In the other 95 cases sternal puncture was performed only when serial thick drops taken at six hourly intervals had proved negative. The author concludes that examination of sternal marrow fluid should be carried out in cases in which repeated examination of the peripheral blood is negative. It elucidates the diagnosis in a number of cases of obscure illness.

Deposition of Protein in Implanted Steroid Hormones.—According to Deaneley and Parkes, crystalline steroid hormones are now often administered by the subcutaneous implantation of pellets made by compression. If a pellet is left

undisturbed in the subcutaneous tissue for some time it becomes in most cases enclosed in a tight connective tissue capsule. The extent to which the capsule prevents continued absorption is not yet clear; on the one hand there is good evidence that tablets may be absorbed at a regular rate throughout their life; on the other hand there are reports that capsule formation may bring to an end the absorption of active material while much of the pellet still remains. A fresh aspect of this problem was raised by Folley, who found that tablets of diethylstilbestrol which had been implanted for an appreciable time acquired, in addition to the connective tissue capsule, an interstitial deposit of protein matter. Folley holds that the interstitial deposit progressively inhibits absorption. Compressed tablets will inevitably have interstices that can be filled with protein, and considerable interest therefore attaches to a recently introduced method of making pellets for implantation by fusing the active substance into solid blocks. The authors have examined the behavior of fused blocks by comparison with that of compressed tablets. In experiments with estradiol, progesterone, testosterone and desoxycorticosterone acetate it was found that tablets made by compression were absorbed, after subcutaneous implantation, at about the same rate as blocks made by fusion. Both types of pellet acquired an interstitial deposit of protein material as described for diethylstilbestrol tablets by Folley, but microscopic examination showed that, whereas the deposit was continuous throughout the tablet, it was superficial only in the block. The formation of the protein deposit is not dependent on the presence of the capsule, as it appears within a few days of implantation, before encapsulation takes place. No evidence was obtained that the interstitial deposit of protein material slows up the absorption of the pellets.

Localized Neuritis of the Shoulder Girdle.—According to Spillane, cases with unusual neuritic features have come to be recognized in the armed forces which were not observed before the war in such numbers. The author himself has seen 20 such cases, and he has studied the records of others. A fairly clear clinical picture emerged of what might be called localized neuritis of the shoulder girdle. In 42 of these 46 cases the onset of the illness was characterized by sharp pain about the shoulder. The painful sites were usually along the upper border of the trapezius, over the spinati and the belly of the deltoid. Pain was sometimes felt along the inner border of the scapula, in the axilla or up the side of the neck. Many patients said it was severe and burning, and nearly all of them needed analgesics. The pain was commonly worse at night and disturbed or prevented sleep. It was aggravated by lying on the affected side and persisted acutely for from three to fourteen days; thereafter it rapidly subsided, but in a few cases a chronic ache was complained of for six or seven weeks. The pressure of braces or the weight of a gun or pack aggravated the discomfort. Pain was more severe in those muscles which subsequently showed atrophy. The muscles affected were the serratus magnus, spinati, deltoid, trapezius, sternomastoid and rhomboids. Effective movements of the shoulder girdle were greatly hampered. The wasted deltoid with paralysis of abduction, the hollowed supraspinous and infraspinous fossae of the scapula and the winging of the scapula, alone or in various combinations, produced a striking deformity of the shoulder girdle. The usual forms of treatment for neuritis did not seem to alter the course of the illness. If these patients are seen for the first time some months after the acute phase, the malady might be mistaken for poliomyelitis. The author differentiates the condition from poliomyelitis and also from acute brachial

radiculitis or neuritis. He considers the possible role of injection neuritis and of repeated minor traumas. The preponderance of rightsided cases and the selective nature of the muscle wasting suggests that "injection neuritis" is not an important factor. It is quite possible that the long thoracic and suprascapular nerves could be injured by carrying a weight (pack and rifle) across the shoulder. Many of these patients, however, were employed in sedentary posts, and 26 of them developed the illness while convalescing in hospital.

Rickettsial Agglutination Studies in Typhus.—Stuart-Harris and his associates made investigations on the serums of patients convalescent from typhus contracted in the Spiddal area of Galway in 1942. Convalescent serums which were collected at intervals of from two to five months after the subsidence of fever were examined for agglutinins to the OX proteus organisms and to murine and epidemic rickettsias. The murine strain was the Wilmington (US) strain, and two epidemic strains were employed, namely the classic Breinl strain first isolated fifteen years ago and a strain recovered from a case of louse borne typhus in Cairo in 1942. Significantly elevated OX 19 titers in excess of 50 were present in 5 of the 9 cases and high OX 2 titers in 2 of these and in 1 other. No case exhibited a high OXK titer. Rickettsial agglutinins were present in 7 serums when examined with the Cairo strain, and 2 of these showed no reaction with Breinl or murine strains. Five of the serums reacted with all three rickettsial strains, and four of these showed a higher titer with the epidemic than with the murine organism, the remaining serum having similar titers with all three strains. The intensity or completeness of agglutination in these 5 serums was also less with the murine than with the epidemic strains, and in 2 instances only traces of agglutination were obtained with the murine organism, whereas both epidemic strains gave 2 plus agglutination. The authors also review observations on the serums of inoculated persons and on animals. They show that until recently the only laboratory method available for the differentiation of human typhus into epidemic and murine types was the classification by guinea pig reaction of the strains of rickettsias recovered from the patients into nonorchitic and orchitic categories. Plotz in 1943 showed by means of the complement fixation reaction that rickettsial antigens could be used to demonstrate specific differences between the two species of rickettsias and that the results with human serums indicated that Brill's disease was serologically related to epidemic rather than to murine typhus. The results of agglutination tests on serums from experimentally infected animals and of absorption tests on these serums indicate that rickettsial agglutination is another possible method of demonstrating specific differences between *Rickettsia prowazeki* and *Rickettsia mooseri*. The application of these findings to human cases of typhus suggests that rickettsial agglutination can be employed to differentiate epidemic and murine typhus and thus to throw light on the epidemiology of the disease. The data indicate that the cases of typhus in Galway were due to *Rickettsia prowazeki*, and this agrees with the observation of McConn that the disease was louse borne.

Chronic Flexner Dysentery Treated with Succinylsulfathiazole.—Caldwell and Hardwick report the history of a woman aged 36 who had chronic schizophrenia. She had had diarrhea and stools positive for Flexner dysentery intermittently for nearly eighteen months before succinylsulfathiazole therapy was instituted. Sulfaguanidine had been tried on four separate occasions without success. Yet after a single course of succinylsulfathiazole her symptoms cleared and the stools became negative for the dysentery bacillus.

Preserved Serum and Plasma in War.—Lang and Schwiegl studied the use of preserved blood under war conditions. Their own experiences cover 92 cases, and in addition they review 258 cases observed by others. The effect of the infusion of preserved blood is the same as that of fresh blood. It is most effective in severe loss of blood and in shock. Not only did it counteract the circulatory collapse in dysentery, but in some cases it also reduced or counteracted the diarrhea. The effect is the same whether serum or plasma is used. The best form of preservation is the dry form. The dry preparations produced by the authors dissolve within a few minutes. To dissolve the dry powder they use the locally available water after boiling and filtration.

- Treatment of Sycois Simplex. R. Wernsdörfer.—p. 521.

Differential Diagnosis of Early Typhus.—Jacobi and Dörschel state that the early diagnosis of typhus is of great importance in the prevention of the dissemination, because if the patient is thoroughly deloused during the first five days dissemination can be completely prevented. The blood sucking louse can obtain the infectious organism from the patient only after an incubation period of from five to seven days. The author observed the development of 108 cases of typhus during the early stages. A positive outcome of the Weil-Felix reaction can be expected from the fifth day on and occasionally from the third day. It definitely indicates typhus from 1:200 and upward. The dry blood agglutination according to Kudicke and Steuer is also valuable. It has the advantage of rapidity of execution. The following symptomatology is always suggestive of typhus: acute onset with fever between 39 and 40 C. within one or two days, severe headaches, ocular pains, redness of the conjunctivas, influenzal throat symptoms, general malaise and extreme weakness. The pulse is usually soft but not frequent. Relative bradycardia together with hypotension is observed in about 75 per cent of the cases. The bradycardia persisted even in the presence of high fever. An exanthem on the soft palate preceded the typhus exanthem in about 70 per cent of the cases. At the same time the entire pharynx is red as in influenza, for which typhus has been mistaken at this stage. Conjunctival injection is seen early in 75 per cent of cases. About 25 per cent of the patients showed signs of meningism. If rigidity of the neck and positive Kernig's sign are present in a patient in whom other symptoms indicate typhus, spinal puncture should be done because epidemic meningitis might exhibit the same initial symptoms as typhus or it may complicate typhus. Bronchitis was present in 80 per cent of the cases. Percussion revealed enlargement of the spleen in all cases. The exanthem appeared between the third and seventh day and it was frequently preceded by marbling of the skin. The spots are pale bluish, in contradistinction to the elevated roseola of typhoid, they are in the skin, not raised above it.

In the later course the exanthem becomes darker, and in the presence of anemia and in dark skinned persons it may not be seen. The differential diagnosis of incipient typhus must consider influenza, pneumonia, abdominal typhoid, measles, epidemic encephalitis, toxemia following freezing, trichinosis, epidemic meningitis, five day fever and allergies.

Diagnosis of Osteosclerotic Anemia.—Binder and Riedl point out that Albers-Schönberg disease or marble bones appears early in life, but this is only the infantile form of osteosclerosis. There is also a form that occurs in adults; but whereas in the infantile form the skeletal changes predominate, in adults the hematologic signs are prominent and the bone changes may remain unnoticed. Wolf has differentiated the following forms of osteosclerosis: (1) osteosclerosis with myeloid leukemia, (2) osteosclerosis with myeloid and lymphoid aleukemia, (3) osteosclerotic anemia, (4) osteosclerosis with panmyelophthisis and fatty degeneration of marrow, (5) osteosclerosis of the newborn and (6) Albers-Schönberg's disease. The authors describe the clinical history of 2 patients in whom the diagnosis was made on the basis of the hematologic aspects and of experiences in the course of sternal puncture, which proved impossible because of extreme hardness of the sternum. One of these patients died; the second one improved after blood transfusion and after that was not heard from again. The authors think that these 2 cases were the first ones in which the diagnosis osteosclerotic anemia was made during life. They describe the roentgenologic aspects of the bones and blood pictures of both patients as well as the postmortem observations on one. The bone tissue showed great density, and there were only remnants of mostly fatty marrow. The authors stress that osteosclerosis has neither a typical blood picture nor uniform hepatic and splenic aspects. Extreme hardness of the sternum is an important diagnostic factor in that it directs further investigations into the correct channels.

Zentralblatt für Chirurgie, Leipzig**69:817-848 (May 16) 1942. Partial Index**

- Surgical Therapy of Central Cervical Fistula. B. Breitner and E. Ruckenstein.—p. 821.
- X-Ray Shadow of Large Solitary Calcification in Spleen. D. von Keiser.—p. 827.
- Prevention of Circulatory Collapse in Lumbar and Spinal Anesthesia. H. W. Pässler.—p. 834.
- Blood Coagulation and Thromboembolism. W. König.—p. 838.

Prevention of Circulatory Collapse in Spinal Anesthesia.—Pässler states that pholedrine (paredrinol or veritol) counteracts the harmful effects of vascular paralysis and thus prevents circulatory collapse. He studied the efficacy of pholedrine particularly in persons of advanced age, in a large number of lumbar anesthetics and in upper spinal anesthetics, the effects of which usually reach to the level of the nipples. Fall in blood pressure could be counteracted in from two to five minutes by an intramuscular injection of from 1 to 1.5 cc. of pholedrine. The systolic pressure, particularly, usually rose considerably higher than the pressure which existed before the anesthesia. The author feels that the object should be not to counteract the circulatory collapse but to prevent it. To accomplish this he gives prophylactically an intramuscular injection of pholedrine immediately after the injection of the anesthetic.

Blood Coagulation and Thromboembolism.—König believes that the synephrin treatment which he recommended in 1933 is still the most widely used measure in the prevention of thrombosis. The success reported by Lenggenhager with heparin (3,800 operations without embolism) induced him to try it. He administered heparin intravenously, usually in four doses, immediately after the operation and eight, twenty-four and thirty-two hours later. In all, 120 adult patients were treated in this manner. The following complications occurred: 2 pulmonary embolisms, 1 pulmonary infarct and 9 severe post-operative hemorrhages and hematomas. The large number of wound complications has discouraged him from further use of heparin. He feels that it is dangerous to interfere with the process of coagulation after operation. In addition to synephrin he employs carbon dioxide inhalation, massage of the legs, exercises and raising of the foot end of the bed.

Book Notices

Manual of Industrial Hygiene and Medical Service in War Industries. William M. Gafar, D.Sc., editor. Issued under the Auspices of the Committee on Industrial Medicine of the Division of Medical Sciences of the National Research Council. Prepared by the Division of Industrial Hygiene, National Institute of Health, United States Public Health Service. [Military Medical Manuals, Volume II.] Cloth. Price, \$3. Pp. 508, with 20 illustrations. Philadelphia & London: W. B. Saunders Company, 1943.

Undoubtedly the Bureau of Industrial Hygiene of the National Institute of Health must have been among the first of the official agencies to notice and respond to the extraordinary stimulus of wartime production. This manual is a reflection of the bureau's experiences in the development and application of environmental hygiene and public health methods to industry in general and to war industry in particular. The first of three sections describes the general details of setting up a medical program in a plant and the essential qualifications and functions of personnel. The discussion of plant medical facilities and medical services is excellent. There is, to be sure, some impatience with traditional methods which are regarded as not to be tolerated under circumstances affecting the efficient conduct of the war effort. At one point, for example, small plants are discouraged from employing physicians on an "on call" fee basis.

Prevention and control of disease in industry is the subject of extended treatment, both from the medical and the engineering standpoint. The contrast in space allotted to the dermatoses and to all other forms of occupational disease is rather striking, although presumably justified on the grounds of case incidence. Case finding is recognized as an important contribution of industrial medicine, especially communicable disease, but by extension the same principle applies to any defect or disability discovered under a program of industrial health examination and conservation. Problems in nutrition, fatigue, plant house-keeping and plant sanitation are all duly regarded as important factors in maintenance of the working force at the highest pitch effective production and safe practice.

The final section of the manual concerns itself with the complexion of the working force and its maximum utilization. It is concluded that every one can perform useful work, at least in some measure, unless illness in the common meaning of the term prevents. Programs for the placement of the handicapped should be conducted with this concept in mind. Employment of women in industry is viewed with equanimity, especially where medical supervision is individualized, since few, if any, occupational exposures have out and out sexual predilections. The final chapter presents all of the pertinent factors associated with sickness absenteeism.

This manual was obviously created to meet urgent wartime requirements. Its convenience and value will persist long after the emergency is over.

Strabismus: Its Etiology and Treatment. By Oscar Wilkinson, A.M., M.D., D.Sc., in collaboration with Richard W. Wilkinson, M.D., M.Sc., F.A.C.S., Instructor in Ophthalmology, George Washington University Medical School, Washington, D. C. Second edition. Cloth. Price, \$4. Pp. 369, with illustrations. Boston: Meador Publishing Company, 1943.

The present edition is thoroughly up to date, including discussion of the recent literature and other evidence of a modern attitude toward the subject. The historical remarks and discussion of anatomy and physiology of the ocular muscles cover the standard material on these subjects. Various theories of etiology are discussed, the author favoring an innervational disturbance as the most important factor in concomitant squint. In the discussion of paralytic squint the various methods of examination are described, but one is left without a very definite idea as to the author's preferred procedure in typical cases. He seems too much inclined to stress the standard diplopia tests without proper emphasis on diagnosis by the deviations on cover test.

While devoting considerable space to orthoptic training, he seems to depend greatly on surgery in treatment. He properly emphasizes the value of very early diagnosis and treatment, including early surgery when necessary. The chapters on surgery show the evidence of a large personal experience, and here the author states clearly his own opinions as to choice of

procedures and the amounts of correction possible with each. He feels it is possible, after careful study of the case, to estimate within fairly narrow limits the amounts of correction possible with each. He cautions against tenotomy of the internal recti, especially in children. Although recognizing the value of recession, for which he employs a technic of his own, he is against bilateral recession, as a rule, as likely to interfere with convergence. He prefers to all other operations his method of resection and often performs it on both external recti at one procedure. Original with the author is a metal brace which is sutured over the opposing muscle after resection to prevent pull on the resected muscle. While familiar with references in the literature to tendon transplantation and the O'Connor cinch, he has apparently had no experience with either procedure. A feature of the book is the series of illustrative cases, well illustrated and showing evidence of careful preoperative and postoperative examination. It well shows the prognostic value of a determination whether true or false retinal correspondence is present. While one might criticize some of the author's procedures in vertical deviations, especially tenotomy of the superior rectus, and could ask for a few more illustrative cases in this category, on the subject of concomitant strabismus the opinions expressed are, in general, sensible and show evidence of good judgment.

In format the book is up to modern standards.

The Reader Over Your Shoulder: A Handbook for Writers of English Prose. By Robert Graves, B.Litt., and Alan Hodge, B.A. Cloth. Price, \$3. Pp. 116. New York: Macmillan Company, 1943.

This is one of the most suggestive and enlightening books on the writing of good English that have come to our attention. Such chapters as "The Peculiar Qualities of English," "The Ornate and Plain Styles" and three chapters on "The Principles of Clear Statement" should be read and reread by every one at all concerned with the production of writing in the field of science. The second half of the book is devoted to examinations and criticisms of the writings of some of the best authors regarding the English they use, including both British and American writers, although only a few of the latter. The author's position, both as a teacher of English and as a competent writer in his own right, is so much a one of leadership that his suggestions may be taken as most authoritative.

Unbidden House Guests. By Hugo Hartnack. Fabrikoid. Price, \$12. Various pagination, with illustrations. Tacoma: Hartnack Publishing Company, 1943.

When the reviewer first saw this book he wondered who would buy it at the excessive price; after reading the book he wondered who would want it at any price. The author uses cumbersome English. He indulges in many digressions from the subject at hand, sometimes in autobiography. He is unduly critical of persons with whom he does not agree. In speaking of the work of the American Medical Association and the articles published in *THE JOURNAL*, he states that they "will continue to be poor as long as no independent work by competent scientists is done in this country." The book deals with various pests, both plant and animal, found within the home and warehouse. Part I is devoted to general matters, such as the damage done by pests, the influence of climate and other conditions on their habits and methods of extermination. Part II, entitled "Plants," includes the bacteria and molds and is rather far fetched. The colon bacillus is not ordinarily considered a household pest, while the statement concerning botulism is erroneous. Part III deals with animal parasites and insects, and part V takes up the vertebrates, such as reptiles, rodents and birds. Part IV is missing. The illustrations are numerous, many of them being of the cartoon variety.

Handbook on Medical Records. By Esther Mayo Hodges-Sherard, A.B., R.R.L., Head of Medical Record Department, Homer G. Phillips Hospital, St. Louis. Second edition. Paper. Price, \$1.50. Pp. 32. Chicago: Physicians' Record Company, 1943.

This little handbook for junior interns and medical record librarians is designed to answer questions relative to the routine for medical records. Much of the material is presented in the form of round table conferences. It is elementary and incomplete but may be helpful as an introductory textbook in some institutions.

Know Your Hay Fever. By A. P. Sperling, Ph.D., Instructor in Hygiene, College of the City of New York. With chapters on Clinical Applications by Arthur B. Berresford, M.D. Fabrirkoid. Price, \$2. Pp. 241, with 13 illustrations. New York: Frederick Fell, Inc., 1943.

For the patient who wants to know a great deal about hay fever this is a good book. It probably contains more information than many patients will want or need, but it is unlikely to disappoint any patient who looks through it for an answer to a question raised by his experience as a hay fever victim.

The book is divided into fifteen chapters, of which the first is a general introductory and explanatory chapter, detailing for the patient the symptoms which he knows all too well. The second chapter is an extensive discussion of pollens and hay fever. Chapters III, IV, V and VI deal with the differentiation of pollens and hay fever into spring, summer and fall varieties and a description of each. This is followed by a chapter on unseasonal or perennial hay fever due to diet, house dust and nonpollen types of sensitization. Then follows a chapter on the character and nature of hay fever in which the mechanism of sensitization is discussed. The next chapter deals not with the nature of hay fever but with the nature of patients and ruthlessly destroys what comfort may have accrued to the victim in the theory that he may be a genius or otherwise set apart on the superior side from his fellow human beings. A chapter is then devoted to theories of basic causes and one to the diagnosis and treatment of hay fever. A chapter follows on hay fever and the elements; that is, climatic influences on hay fever and its victims. Hay fever in various parts of the world other than the United States is described, and there is a chapter devoted to the characteristics of various well known hay fever resorts. Finally there is a disproportionately long and to the lay person not particularly useful section on research and the history of hay fever.

In general the material is excellent. It could have been presented more effectively in fewer words, and there is a question whether some of the more technical aspects have a true place in a book written for lay consumption. The section on hay fever resorts is good as far as it goes, but this reviewer, himself a hay fever victim, could have added a number of localities not mentioned by the authors. In connection with this listing of hay fever resorts, insufficient use was apparently made of maps and listings of pollen counts which have been in the literature for a number of years. To be specific, localities in Wisconsin, on the north shore of Lake Superior, are not mentioned. Minnesota's Arrowhead coast is mentioned only as a "probable" hay fever resort, whereas the fact is that it is known throughout the Middle West as excellent in this regard. This middle western area is designated as "remote." To an Easterner undoubtedly it is.

The Mechanics of Obstetrics. By Norris W. Vaux, M.D., Professor of Obstetrics, Jefferson Medical College, Philadelphia, and Mario A. Castallo, A.B., M.D., F.A.C.S., Assistant Professor of Obstetrics, Jefferson Medical College. Cloth. Price, \$4. Pp. 217, with 200 illustrations. Philadelphia: F. A. Davis Company, 1943.

This small textbook has been written as a manual for a course in manikin obstetrics. The first few chapters are devoted to the female pelvis, the fetus, presentation and position, and labor. Pertinent facts are presented in outline form. The mechanism of normal and the various abnormal presentations are described and illustrated. The indications and conditions of the common obstetric operations are enumerated and their technic is described. The manual will serve admirably in conjunction with a manikin course. The wisdom of demonstrating operative procedures to medical students is open to question. It is the feeling of many teachers that student teaching should be limited to normal obstetrics.

Huber the Tuber: A Story of Tuberculosis. By Harry A. Willmer, B.S., M.S., M.D., The University of Minnesota Medical School, Minneapolis. Introduction by J. Arthur Myers, Ph.D., M.D. Second edition. Cloth. Price, \$1. Pp. 83, with illustrations by the author. New York: National Tuberculosis Association, 1943.

This book, originally published in 1942, has been taken over by the National Tuberculosis Association and is being circulated for the great value it possesses in educating the coming generation regarding this disease. John Kieran found it both educational and hilarious. Its cleverness makes the acquiring of knowledge regarding tuberculosis easy and interesting.

Encyclopedia of Substitutes and Synthetics. Edited by Morris D. Schoengold. Cloth. Price, \$10. Pp. 382. New York: Philosophical Library, 1943.

This unique encyclopedia presents invaluable information that is not available even in the best libraries without thorough time consuming searches through the literature. The material is arranged in alphabetical order from Abalyn to Zola. Each compound is defined, and its properties, uses and substitutes are listed. Assistance was provided to the editor by seventy-five firms and four government agencies. The material is presented in a concise and readable manner and cross indexed adequately in an index of trade names and a subject index. Perhaps there is no other field of investigation that has caught the public's fancy to a greater degree than has the development of substitute and synthetic materials. This book will prove of great value to manufacturers, researchers and teachers. Its usefulness to the medical profession is evident, but it would be of added value if brief discussions on toxicity were included. Perhaps if the book progresses to a second edition a competent person or group will be invited to supply such information.

Sex in Marriage. By Ernest R. Groves, Professor of Sociology, University of North Carolina, Chapel Hill, and Gladys Hoagland Groves. Third edition. Cloth. Price, \$2. Pp. 224, with 5 illustrations by Robert L. Dicklason, M.D. New York: Emerson Books, Inc., 1943.

The third edition of this useful book retains the valuable features of earlier editions, which have enjoyed well deserved success. The book contains chapters on sex and happiness, the background of sex attitudes, sex before marriage, the sex equipment, the beginnings of marriage, the love art of the husband, the love art of the wife, some common sex problems of marriage, planned parenthood, sex and life, and books suggested for additional reading. The book is written out of the long experience of the authors with marriage and family counseling, in which they have been exceptionally successful. They have succeeded in the difficult task of giving fully all necessary information without falling into the danger of producing merely another example of erogenous reading. The Dickinson diagrams with explanatory notes are helpful. This edition can be recommended with as much confidence as its predecessors.

Methods of Treatment. By Logan Clendenning, M.D., Clinical Professor of Medicine, Medical Department of the University of Kansas, and Edward H. Hashinger, A.B., M.D., Clinical Professor of Medicine, Medical Department of the University of Kansas, Kansas City, Kansas. Eighth edition. Cloth. Price, \$10. Pp. 1,033, with 135 illustrations. St. Louis: C. V. Mosby Company, 1943.

This big book evidently has met a need and has satisfied thousands of physicians. It covers a huge field, including such branches as pediatric treatment, physical therapy, hydrotherapy and anesthesia. Doubtless wisely, the two main authors have got a number of men to help them in writing special chapters. The book is to be recommended. As would be expected from the fact that Clendenning is editor, the English flows easily.

Biochemistry for Medical Students. By William Yeale Thorpe, M.A., Ph.D. Third edition. Fabrirkoid. Price, \$4.50. Pp. 476, with 39 illustrations. Baltimore: William Wood & Company, 1943.

This synopsis of biochemistry, intended to be complementary to textbooks of physiology, contains sufficient material in condensed form to enable one to understand physiologic and biochemical processes. On one hand it contains much information for its size, on the other it lacks important details which would excite interest in reading. Cross references help to keep the book concise. It is a good attempt to give an outline of biochemistry to medical students in order to facilitate study for examinations.

Births, Infant Mortality, Maternal Mortality, 1940. Graphic Presentation. U. S. Department of Labor, Children's Bureau, Publication No. 288. Boards. Pp. 31B, with illustrations. Washington, D. C.: Government Printing Office, 1943.

This is a table of charts and accompanying maps giving births, infant mortality and maternal mortality in the United States and the several states for the year 1940. It is a strictly factual presentation, without any endeavor to account for the facts which it sets forth. It is a convenient and graphic reference compilation which should be useful to health officers, sociologists and others having to do with public health and welfare, particularly in the field of infancy and maternity.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

LACTATION IN MEN

To the Editor:—During a recent discussion I made the statement that it was possible under certain circumstances for a male to nurse a child, having read somewhere that this custom was present among a certain savage tribe. I believe that the male breast is similar to the female in a rudimentary form and that it would be possible by certain stimulation for milk to be produced without the individual necessarily being abnormal, i. e. without any endocrine dyscrasia.

M.D., New York.

ANSWER.—Several procedures are known to be used in primitive societies in order to induce lactation in men as well as in virgins and postmenopausal women. The lactogenic treatment most frequently used in these primitive tribes has consisted in direct application of irritating leaves to the breasts or, more simply, in making the infant suckle the mammary glands. It is quite possible by these procedures to produce galactorrhea, i. e. a flow of a milky or serous-milky mammary secretion. A similar phenomenon may occur spontaneously under certain physiologic conditions, such as the menopause. This secretion is, however, quantitatively and qualitatively inadequate for the infant's nourishment and growth. No instance of true lactation induced by these artificial means has ever been reported. True lactation is a rather complex and not well understood process requiring full growth of the epithelial ducts, development of the lobule-alveolar system and secretory activity of the alveolar cells of the mammary glands. These changes are the result of the interaction of a number of endocrine factors produced by the pituitary, adrenals, ovaries and placenta. Attempts to reproduce by means of synthetic endocrines the endocrine picture which is known to occur during the period of pregnancy and nursing have so far failed to induce lactation in nonpregnant men even when it leads to growth and engorgement of the mammary glands. Hence the fact that the male breast contains a system of patent ducts and rudimentary alveoli does not constitute evidence in the present state of knowledge that lactation can be produced in males. The few instances in which a milky discharge occurs in males are associated with evident endocrine disturbances such as pituitary chromophile tumor and, exceptionally, adrenal cortex carcinomas.

PAPILLARY LESIONS ON INFANT

To the Editor:—A 6 months old baby girl, white, had a lesion on the inner aspect of the arm just below the axilla. It was a papillary growth about 1.5 cm. in diameter and elevated about 1 cm. It looked just like a good many epitheliomas which I have had occasion to see. The baby also had six or eight smaller lesions on the scalp which looked more like boils not yet ready to open. There were several palpable cervical nodes. The general health and appearance of the baby were good. The mother stated that she fed well and apparently had no fever and was gaining weight. I treated the lesion on the arm with superficial x-rays, giving about 1,000 roentgens well shielded. This was about a month ago. Since that time I have repeated the procedure twice after getting the pathologist's report of a tuberculous granuloma. The section was taken just before the first treatment. The lesion has improved greatly since these three treatments. The scalp lesions may have grown a little but not rapidly. The mother states that one or two new lesions have appeared on the scalp. What shall I do about the scalp lesions? What is the probable prognosis in regard to the child? Should I take further steps to prove the diagnosis? The specimen was sent to a good pathologist, who did not seem doubtful of the diagnosis.

R. N. Long, M.D., Selma, Ala.

ANSWER.—It is impossible to make a definite diagnosis in this case without more information than is presented in the query. General pathologists sometimes need the help of experts in dermatologic histology in order to arrive at a better conclusion about cutaneous changes. It is quite possible that the lesion on the arm was, in fact, one of tuberculosis. Because of the papillary character of the lesion it could have been an example of tuberculosis verrucosa cutis. The other lesions on the scalp suggest sarcoidosis. These lesions do not break down and remain for some time before involuting. Their general histologic character resembles somewhat the changes present in tuberculous tissue. However, while there is a resemblance, the two disorders usually can be distinguished readily. Another possibility is that the scalp lesions are juvenile xanthomas. These may occur early in life and may look something like those described for this infant. It would be well to have a competent dermatologist examine this baby to arrive at a more certain diagnosis.

PHENYTOIN SODIUM FOR EPILEPSY

To the Editor:—A man aged 40 had an automobile accident about twenty-five years ago in which he suffered a fractured skull requiring trephining and ligation of an artery, from all of which he seemed to recover completely. About two years ago, twenty-three years after the accident, during a period of worry over business affairs, he had a typical epileptic seizure followed by a second a few weeks later. The patient was given capsules of phenytoin sodium and has not had any attacks since the two mentioned. However he has continued to take the phenytoin, one capsule daily. Does the prolonged use of phenytoin have any deleterious mental effect? Is it advisable to continue the capsules of phenytoin in doses of one capsule daily? Should the dose be reduced? How long should they be continued and in what doses?

M.D., Pennsylvania.

ANSWER.—Phenytoin sodium has been used regularly in some thousands of cases, and no mental deterioration has been reported. Indeed, in many "idiopathic" cases there is an improvement in the intelligence. The dosage employed is small and should not be reduced; usually the effective dose is close to the toxic dose, and this may be as high as 0.6 Gm. daily. Usually treatment with any anticonvulsant has to be continued indefinitely, as the effect of the drug is purely symptomatic; but a trial without it may be made at the end of three years, especially if electroencephalography shows a normal or nearly normal pattern.

PRECOCIOUS ADOLESCENCE AT 17 MONTHS

To the Editor:—A boy aged 17 months is rugged, active and normal in every way except that his penis is much larger than normal and hair is developing at the base. Can you name the cause and suggest any treatment if it is a known disease?

Joseph I. Grover, M.D., Dorchester, Mass.

ANSWER.—The patient described shows evidences of precocious adolescence, which has been attributed by different students to disturbances of the pituitary, sometimes involving neoplasm, or to disturbances of the pineal gland, the thymus or the adrenal cortex, or to atypical development of gonadal tissue. Rather extensive examination will be necessary in order to decide which of these is involved. At the age of 17 months this will not be too easy, but the problem is urgent because of the probability at this age of neoplasm in one of the areas mentioned. The patient should be seen in consultation by some clinician with wide experience in this differential diagnostic field before any attempt at treatment is made.

TRANSFUSION AND HYPERTENSION

To the Editor:—Will you kindly tell me whether there is any substantial reason for the use of blood plasma or whole blood transfusion in an attempt to reduce hyperpiesia?

M.D., Ill.

ANSWER.—There is no rational basis for the use of blood plasma or whole blood transfusion in order to reduce hyperpiesia. Possibly the inquirer had in mind that, by transfusion, antipressor substances might be conveyed to the recipient; but the amounts transferred in this way would certainly be too minute to have any appreciable effect.

The blood pressure of hypertensive or even normal persons will be increased if transfusions are given in large enough doses and frequently enough, on account of the increased blood volume and, when whole blood is given, also from the induced polycythemia. A well recognized treatment for hypertension is venesection, not transfusion, though the beneficial effects of the former procedure are only temporary. In fact, under ordinary circumstances severe hypertension would be a contraindication for blood transfusion because a further increase in blood volume in such patients could bring about a condition dangerous to life. If it is desired to transfuse an anemic hypertensive patient, exsanguination transfusion should be carried out, in which blood is withdrawn from one arm at the same time that the blood is infused in the other.

THERAPY FOR MUCUS OF ASTHMA

To the Editor:—Is there any remedy that will reduce the amount of sticky consistency of the mucus in asthma? I have used potassium iodide, ammonium chloride, fluidextract of lobelia, antipyrine, ephedrine sulfate, epinephrine, aminophylline and whooping cough antitoxin.

George H. Heitmuller, M.D., Washington, D. C.

ANSWER.—A prescription consisting of apomorphine hydrochloride 2 grains (0.13 Gm.), potassium iodide 5 drachms (20 Gm.) and syrup of cherry to make 4 ounces (120 cc.) taken in a dose of 1 teaspoon every four hours has been found useful in reducing the sticky consistency of the mucus in asthma. Intravenous injections of 7½ grains (0.5 Gm.) of aminophylline mixed with 1,000 cc. of 5 per cent dextrose have also been of aid, and in many cases 1 cc. of epinephrine plus a liter of 5 per cent dextrose intravenously has promptly relieved the attack. Intravenous injections of 10 cc. of aminophylline (3¾ grains, or 0.25 Gm.) have also been of great help.

MONTREAL

Administration of desoxycorticosterone acetate in comparatively high doses causes nephrosclerosis with increased blood pressure and disturbances in electrolyte metabolism, a fact which has been demonstrated in the chick, dog, cat, rat and monkey. Unilateral nephrectomy and a high intake of sodium chloride facilitate the production of these toxic actions of desoxycorticosterone acetate.¹ In addition to the nephrosclerosis, the most striking features of this overdosage are the formation of "Aschoff bodies" in the heart and the presence of periarteritis nodosa,² a condition occasionally seen in man following an attack of rheumatic fever. Since in addition choreiform twitches and a few rare cases of arthritis were also encountered in desoxycorticosterone acetate treated animals, it may be said that all the elements of the complex rheumatic syndrome were reproduced in the experimental animal. However, the great frequency of joint manifestations in the spontaneous disease of man and its comparative rarity in the experimentally elicited syndrome remained inexplicable. The main object of this communication is to show that changes in the internal medium of the body may determine the localization of the noxious effects of desoxycorticosterone acetate in the joints. This view is supported by observations showing that the arthritic lesions, which are rarely seen in the intact desoxycorticosterone acetate treated rat, develop with great frequency in similarly treated thyroidectomized or adrenalectomized animals especially if these are kept in cold surroundings. Indeed, under such conditions the joint changes

may be evident at a time when none of the other morphologic manifestations of desoxycorticosterone acetate overdosage have as yet become conspicuous.

EXPERIMENTAL

Since our previous experiments revealed that unilateral nephrectomy and sodium chloride treatment increase the sensitivity of rats to many overdosage effects of desoxycorticosterone acetate, all animals of the first experimental series were sensitized by ablation of the left kidney five days before injections were started. Instead of ordinary drinking water, all animals were given a 1 per cent aqueous sodium chloride solution beginning on the day of operation. Twenty-eight female albino rats, weighing 40-60 Gm., were used for this experiment. Ten of these were bilaterally adrenalectomized and 10 were thyroidectomized simultaneously with the ablation of one kidney, while the remaining 8 served as controls having intact adrenals and thyroids. All three groups received 2 mg. of finely ground desoxycorticosterone acetate crystals subcutaneously twice daily in an aqueous suspension containing 20 mg. per cubic centimeter. Their food consisted of "purina fox chow," which was complemented in the case of the thyroidectomized animals by the administration of calcium lactate powder ad libitum in order to compensate for possible parathyroid deficiency due to ablation of the internal parathyroids.

Signs of arthritis (figs. 1-3) were first noted on the fourteenth day of desoxycorticosterone acetate treatment, at which time 6 animals in the adrenalectomized group and 2 in the thyroidectomized group exhibited hyperemia and swelling in the tarsal joint region of one or both hind feet. Only occasionally did we note any macroscopically prominent swelling in other joints. The swollen regions were tender to touch. Subsequently the swelling tended to disappear and reappear somewhat irregularly, but with definite predilection for the joints of the hind feet. It should be noted that on the fourteenth day of treatment, when these joint lesions were first observed, 2 animals of the adrenalectomized group and 7 of the thyroidectomized group had succumbed from pneumonia or thyroparathyroid deficiency. In the desoxycorticosterone acetate treated control group of this series only 1 rat showed signs of mild arthritis on the fourteenth day and, while this animal recovered during the subsequent course of the experiment, another showed moderate arthritic manifestations on the twentieth day of treatment. On this day all surviving animals were killed. At autopsy macroscopic signs of nephrosclerosis, periarteritis nodosa or rheumatic nodules in the heart were observable in almost every animal of all three groups, there being no clearcut correlation between the arthritic manifestations and the

of the lesions in the internal organs. The knee joint and one entire hind foot from each animal were taken for section. The histologic changes in these tissues will be discussed simultaneously with the corresponding material of our second experiment, which appeared to be essentially the same.

For this series 34 female albino rats, weighing 30-50 Gm., were used. All were sensitized by ablation of the left kidney and were given 1 per cent aqueous sodium chloride solution to drink on the day injections were started. We subdivided them into four experimental groups, one consisting of 10 bilaterally adrenalectomized and the second 10 thyroidectomized animals, with two control groups of 8 desoxycorticosterone acetate treated and 6 nontreated rats. The first mentioned three groups received two daily subcutaneous injections of 3 mg. of finely ground desoxycorticosterone acetate crystals in an aqueous suspension containing 30 mg. per cubic centimeter, while the fourth group received no treatment. Their diet was the same as that of the first experimental series.

The swelling was most evident in the tarsal or ankle joint region and was usually accompanied by hyperemia. Although the total number showing arthritis during the experiment was 4 in group 1, 4 in group 2 and 3 in group 3, it should be emphasized that the severity and duration of the articular lesions was much greater in groups 1 and 2 than in group 3. None of the animals of the nontreated control group ever showed any arthritis. Most deaths during the experiment were due to pneumonia. All surviving animals were killed on the twenty-sixth day. At autopsy macroscopic signs of nephrosclerosis, periarteritis nodosa or rheumatic nodules in the heart were, generally speaking, more pronounced in the adrenalectomized and thyroidectomized than in the intact desoxycorticosterone acetate treated rats and were absent in all noninjected, partially nephrectomized controls.

In view of the fact that both adrenalectomy and thyroidectomy seriously disturb thermoregulation, a group of 6 adult rats treated essentially as those of

the accompanying table. The arthritic manifestations subsided and recurred in the same joint or subsided in one joint only to reappear in another articulation of the same animal.

group 1 of the preceding experiment for fourteen days, but showing no signs of arthritis, was placed outdoors for twenty-four hours on a cool, windy November day. At the end of this period 3 animals had succumbed and 1 of these, as well as all survivors, had enormous tarsal swellings of the type described.

These observations, as well as the fact that in the two preceding experimental series arthritic changes occurred suddenly in a large number of animals on days when the temperature in the animal room happened to fall below the usual, leads us to assume that temperature changes play an important role in the pathogenesis of the arthritis.

A histologic analysis of the joint lesions—which were essentially identical in all groups—revealed them to be surprisingly similar to those seen in acute cases of rheumatic polyarthritis in man. Comparatively few such cases come to autopsy, but an excellent description of their pathology will be found in a pertinent com-

munication by Fahr.³ In our experimental material the acute cases show pronounced edema of the periarticular connective tissue and synovial villousities, generally accompanied by hydrarthrosis (figs. 4 and 5). In a somewhat more advanced stage the mesothelial lining of the synovial membranes disintegrates and the underlying tissue undergoes a process of hyalinization

develops which may become very cellular in some cases (fig. 7). It consists of immature large fibroblast-like, slightly basophilic cells containing voluminous vesicular nuclei. The outlines of these cells are irregular and ragged, and most of them contain only one nucleus, although some are polynuclear and resemble "Aschoff cells." While all these changes are very similar to

Fig. 4.—This and all subsequent photomicrographs represent sections of the metatarsal region in adrenalectomized desoxycortico-terone acetate treated rats of the first experimental series, described in the present communication. The section shows the appearance of a normal joint which shows no pathologic change in spite of treatment. Note the thin synovial membrane and the regular appearance of the underlying connective tissue. The joint cavity contains no pathologic constituents.

Fig. 8.—Normal compact metatarsal bone (A) and newly formed periosteal bone (B) in a comparatively chronic case of arthritis.

Fig. 9.—Normal striated muscle fibers (top) and granulomatous nodule (bottom) from a muscle in the metatarsal region. The muscle fibers at the border of the nodule have undergone degeneration (A).

and necrosis (fig. 6). At the same time fibrinoid necrosis is also seen in the tendon sheaths and the subcutaneous tissue of the periarticular regions. Around these hyaline fibrinoid deposits a granulation tissue

those seen in rheumatic fever, we should also like to record the frequent occurrence of large round eosinophilic cells with a small dense nucleus within the granulomatous area. The exact nature of these cells is still under investigation, but they do not appear to have been seen in man.

3. Fahr, T.: Beiträge zur Frage der Herz- und Gelenkveränderungen bei Gelenkrheumatismus und Scharlach, Virchows Arch. f. path. Anat. 232: 134, 1922.

In still more advanced cases the edema subsides almost completely and the granulomatous tissue becomes increasingly dense. Infiltrations are also noted in the sheaths of the nerves in the affected regions. This may perhaps partly explain the painfulness of the lesions. Where hyalinization and granuloma formation occur in the immediate vicinity of the periosteum, new bone formation is stimulated. In such regions it appears that the eosinophilic fibrinoid deposits are gradually transformed into osteoid tissue, while the surrounding immature fibroblasts change into osteoblasts. As a result of this process, rather irregular callus-like bone proliferations arise in the periarticular regions. These changes are strikingly similar to those of the chronic hypertrophic arthritides (fig. 8). The striated muscles between the tarsal bones are frequently infiltrated by nodules of granuloma tissue similar to that seen in the synovial villi and the surrounding connective tissue. In the vicinity of such nodules the muscle fibers undergo degeneration (fig. 9).

Subcutaneous nodules, which are so characteristic of rheumatic joint diseases in man, are not very typical in our experimental animals, mainly because the subcutaneous foci tend to coalesce, thus forming rather diffuse infiltrations which may extend into the derma proper. In some instances these are reminiscent of the proliferative stage of scleroderma.

Although the knee joints did not show any obvious swelling or other macroscopically detectable change in the animals of these groups, microscopic examination revealed massive infiltration of the panniculus adiposus by a granuloma tissue similar to that seen in the vicinity of the arthritic joints of the foot. Other joints have not been examined microscopically but, judged by the lesions in the knee, it is quite possible that several articulations which showed no macroscopic change were similarly affected and sensitized by the treatment in such a manner that additional local damage (draft, cold and the like) might have provoked acute phenomena in their infiltrated tissues.

In conclusion it should be mentioned that the joint cartilages themselves were not visibly affected in any of our animals. This may explain the fact that the arthritis often regresses without leaving any permanent disability. It will be noted that in this as in most other respects the experimental joint lesions elicited by desoxycorticosterone acetate are strikingly similar to those observed in spontaneous rheumatic fever.

COMMENT

Among the various factors which were combined to produce arthritis in these experiments, the causative agent appears to be the corticoid hormone desoxycorticosterone acetate. Exposure to cold, thyroidectomy or adrenalectomy greatly facilitated the production of joint lesions but were effective only as predisposing agents. Indeed, even at room temperature desoxycorticosterone acetate had produced arthritis in a few of the animals that were neither thyroidectomized nor adrenalectomized. Furthermore, the characteristic morphologic lesion of rheumatic fever, the Aschoff nodule, was found in the heart and elsewhere after very long desoxycorticosterone acetate treatment even in the absence of organ extirpation or salt administration.⁴

The clinical and histologic similarity of the arthritis observed in our animals with that seen in the acute

rheumatic fever of man suggests that the human disease may be a clinical manifestation of adrenal cortex hyperactivity. It has often been emphasized that rheumatic fever, as well as nephrosclerosis and hypertension, tend to develop following exposure to a variety of rather nonspecific damaging agents such as exposure to cold, emotional shock and infectious diseases. On the other hand, these same agents are known to cause adrenal enlargement with histologic signs of increased cortical hormone production, a phenomenon characteristic of the "alarm reaction."⁵ It has even been found that immediately after exposure to various types of stress the corticoid hormone content of the urine rises above normal.⁶ It has also been demonstrated in rats that concomitantly with the adrenal cortex hypertrophy similar exposure to damaging agents (especially cold) causes nephrosclerosis with hypertension and that here again unilateral nephrectomy and treatment with sodium chloride exert a sensitizing effect.⁷ Although it is too early as yet to give a definite interpretation to these observations, it may be said that they are compatible with the assumption that exposure to various damaging agents stimulates the production of corticoid hormones by the adrenal cortex. This is probably a defense mechanism, since these compounds increase resistance in general. However, under certain conditions this defense reaction may defeat its purpose, as the resulting endogenous overproduction of corticoids may elicit changes similar to those produced by the exogenous administration of desoxycorticosterone acetate. Evidently this endogenous corticoid overdosage would be most detrimental to patients who are sensitized to the toxic actions of cortical hormones by renal disease or a habitually high intake of sodium chloride.

In the light of this preliminary discussion, it appears that the role of cold, thyroid or adrenal deficiency would be to favor a localization of the desoxycorticosterone acetate action in and around joints. It is not clear as yet why the joints and the periarticular tissues should become more readily affected by desoxycorticosterone acetate in the absence of either the adrenals or the thyroid, but the detrimental effect of these gland deficiencies on thermoregulation may be involved. At any rate, the present observations show that complex interrelations exist between the endocrine glands and the joints and that the adrenal and thyroid exert a demonstrable effect on the articulations.

In view of the great frequency and social significance of arthritic lesions in man,⁸ it appears desirable to correlate our experimental findings with those recorded in clinical papers. The most striking fact which emerged from a perusal of the voluminous literature on arthritis was that, in spite of the countless recorded observations of joint lesions in patients suffering from various endocrine diseases, no investigator presented

4. Selye, Hans.: Unpublished data.

a unified concept of their pathogenesis. In the absence of any systematic review of the relevant literature, we should like to summarize the data on "endocrine arthritis" in order to expedite further clinical investigations in this field. The rheumatic and rheumatoid joint lesions will be considered together, and we shall not try to differentiate sharply between the various types of chronic arthritis (hypertrophic, atrophic, and so on). As suggested by some of our results (compare figures 2 and 3), it appears quite possible that, depending on the acuteness or chronicity of the condition or other incidental factors, the same etiologic agent may manifest itself in different ways and give rise to different types of arthritis. However, the purulent arthritides with demonstrable microbial contamination of the joint cavities will not be considered here, as they are obviously not of endocrine origin.

For the evaluation of our experimental results, special interest is attached to those clinical observations which tend to correlate arthritis with thyroid or adrenal deficiency. Hypothyroidism appears to influence the joints in a rather specific manner. Since Kocher⁹ developed his concept of "rheumatismus thyreoprivus chronicus," the frequency of rheumatic and especially rheumatoid conditions in frank myxedema and latent hypothyroid conditions has been established by numerous observations.¹⁰ In those cases in which arthritis appears in combination with signs of thyroid deficiency and a decreased basal metabolic rate, thyroid medication often proved of great value.¹¹

Although clinical observations also reveal the possibility of producing arthritis with thyroid hormone¹² we have been unable to do so in animal experiments up to the present. However, it is perhaps pertinent to mention that thyroxin overdosage is effective in causing nephrosclerosis and hypertension especially in the unilaterally nephrectomized sodium chloride treated rats and in this respect resembles desoxycorticosterone acetate overdosage.¹³

A deficiency of the adrenal gland has not been seriously considered by clinicians as playing a role in the production of arthritis, although in Addison's disease¹⁴ and in status thymicolymphaticus¹⁵ arthritis has been recorded.

Surprisingly, joint lesions have also frequently been reported in cases of either thyroid or adrenal hyperactivity. Thus frank toxic diffuse goiter is often accompanied by acute or chronic arthritis and in such cases thyroidectomy or x-ray treatment of the thyroid region

proved beneficial.¹⁶ Similarly chronic arthritides are frequent complications of Cushing's disease in which the adrenal cortex is usually hyperplastic or adenomatous.¹⁷ In conclusion, the most prominent fact about the clinical syndrome of endocrine arthritis is that both hyperfunction and hypofunction of several endocrine glands may elicit joint manifestations.

Among the joint lesions which do not appear to be directly related to the thyroid or adrenals, the chronic arthritides, periarthritides and arthralgias of the menopause received particular attention because of their great frequency and practical importance.¹⁸ According to Charcot¹⁹ 8 to 10 per cent of women between 40 and 60 years of age suffer from arthritis as against 1 to 2 per cent of old men. Among 1,000 menopausal women investigated by the Council of the Medical Women's Federation²⁰ 23.7 per cent exhibited evidence of "arthritis and fibrositis." The British Ministry of Health points out that between the ages of 37 and 54

anticipated and, furthermore, as a rule the rise that was obtained proved to be only temporary."

On the other hand, Rosenthal's experimental studies⁹ suggest that electrolyte solutions deserve reconsideration. In an extensive series of well controlled experiments in mice, Rosenthal recently found that in acute burn shock "mouse serum intravenously was slightly less active than equivalent volumes of 0.9 per cent NaCl orally. Little effect was observed from the intravenous administration of a hypertonic solution of human serum albumin. . . . it is possible to correlate the degree of effect of this preparation and of mouse serum with the sodium contained in the doses administered. . . . It was demonstrated that serum was slightly more effective when given orally than

Fig. 2.—Changes in the blood after treatment with oral sodium lactate in patient W. R. with extensive full thickness burns (weight 64 Kg). Horizontal axis, time after the burn: hours up to forty eight, then time in days. Vertical axis, percentage change in hematocrit, plasma proteins and chlorides from the normal range, which is indicated by the center horizontal line. This "normal" line represents hematocrit value of 45 per cent, plasma protein of 7 Gm. per hundred cubic centimeters and plasma chlorides of 103 milliequivalents per liter. The amount of sodium lactate solution administered is shown in the upper left border of the chart. Solid line, hematocrit; dotted line, plasma chloride; broken line, plasma proteins. The chart shows the progressive rise in hematocrit after the severe burn, the decrease in plasma proteins with subsequent increase on the fifth day without administration of any plasma and the decrease in plasma chlorides, which remained low for fourteen days.

intravenously."^{9a} Saline solution intravenously was less effective than by mouth; isotonic dextrose solution was without effect.¹⁰ It is of interest that in 1926 Davidson¹¹ wrote of "the indefinite term 'shock'" and "the equally vague term 'toxemia of burns'" when he described the "striking alteration of chloride metabolism in cutaneous burns." On the basis of his observations, that the plasma chlorides of such patients were low and the urine almost devoid of sodium chloride for as long as three weeks after the burn, in spite of adequate salt intake, he advised the administration of sodium chloride in severe burns instead of dextrose solutions.¹² In extensive burns he administered as much as 10,000 cc. of isotonic saline solution in twenty-four hours by three routes: subcutaneous, intravenous and rectal.¹³

Since extensive third degree burns were being studied to evaluate a new local therapy,¹⁴ it was decided on the basis of these facts to try treating burn shock with oral sodium lactate¹⁵ instead of plasma. The results with this simplified therapy have proved so successful that this preliminary report is presented.

PROCEDURE

The procedure used in this study is briefly as follows: Morphine sulfate $\frac{1}{4}$ grain (0.016 Gm.) by hypodermic injection was administered on admission for severe pain (less to children). Blood was taken at once for immediate and subsequent analyses. The patient was placed on and covered with a sterile sheet, but no blankets nor heat were applied.¹⁶ Large amounts of the chilled isotonic (one sixth molar) 1.75 per cent sodium lactate solution were given by mouth at once and at fifteen minute intervals thereafter on schedule. This solution was prepared by emptying a bottle previously filled with 72 Gm. of sodium lactate syrup into a 4 liter bottle, which was then filled with cold tap water. Sodium lactate syrup varies in composition, frequently containing but 60 to 65 per cent of sodium lactate, in which case 110 Gm. is used. Storage of large quantities of the isotonic solution, which may become sour, was thereby avoided. The burns were rapidly freed of any loose tissue, covered with the local application¹⁷ and bandaged. Blood pressures and repeated samples of blood were taken at frequent intervals during the first twenty-four hours. A careful record of fluid intake is imperative, and an exact schedule is used so that approximately 7 to 10 liters (from 10 to 15 per cent of body weight) of the isotonic sodium lactate are administered within the first twenty-four hours. Any vomiting (which frequently occurs in severe burns¹) was treated by administration of more fluid. Frequently a small Levine tube was passed through the nose and connected with a drip apparatus, so that the sodium lactate was administered constantly. The urinary output was carefully watched and all urine collected. Fluid administration in the subsequent days was adjusted to obtain 1 to 2 liters of urine daily. When food was tolerated, a high protein diet was given supplemented in extensively burned patients by 50 to 100 Gm. daily of amino acids.¹⁸

¹⁸ Sodium lactate was selected in the beginning because in Rosenthal's⁹ experiments it appeared slightly superior to other sodium salts. Although this superiority may be negligible, we have continued to use lactate because it is well taken by adults, does not seem to provoke vomiting and yields the satisfactory results referred to in this paper. It also helped to counteract the acidosis and to induce formation of an alkaline urine, thereby avoiding renal precipitation of sulfonamides (Fox, C. L., Jr.; Jensen, O. J., and Mudge, G. H.: The Prevention of Renal Obstruction During Sulfadiazine Therapy, J. A. M. A. 121: 1147 [April 3] 1943). The extent of conversion of lactate to bicarbonate is yet uncertain, but no chemical nor clinical evidence of alkalosis was noted in our cases. A more physiologic solution would contain sodium chloride. Such solutions are under study at the present time.

¹⁶ Rosenthal, S. M.: Effects of Local Therapy on Mortality from Shock, Pub. Health Rep. 57: 1923 (Dec. 18) 1942. Environmental Temperature and Mortality in Burns, editorial, J. A. M. A. 121: 1353 (April 24) 1943.

¹⁷ The local treatment of these patients consisted in the application of neutralized (pH 7.6) tannate-sulfadiazine ointment,¹⁴ which was covered with a layer of sterile old linen, then overlaid with gauze pads and bandaged snugly but not tightly, i. e. a "pressure" bandage was not used. This ointment contains 5 per cent of tannic acid as neutral tannate and 3 per cent of sulfadiazine or sulfathiazole as soluble salts, both made by addition of sufficient alkali to raise the pH to 7.6. This mixture is then added to a water soluble stearate base with a continuous aqueous phase. The W. R. Warner Company compounded this ointment for us.

¹⁸ The oral amino acids (Oramin) were generously provided by the William R. Warner Company, New York. Although some of these patients were in bed for four months and underwent up to eight skin grafting operations, their plasma proteins were maintained with only occasional preoperative transfusions; no malnutrition edema was encountered.

¹³ Davidson, E. C.: Tannic Acid in the Treatment of Burns, Surg., Gynec. & Obst. 41: 202 (Aug.) 1925.

Blood samples were analyzed by "hematocrit" for relative cell volume and the plasma for total protein, albumin:globulin ratio, chlorides, carbon dioxide combining power, sodium, cephalin flocculation capacity, amylase, icterus index, direct and indirect bilirubin, sugar and urea. The urine was analyzed for sodium, chlorides, sulfonamide, tannates, creatinine and creatine.

RESULTS

All cases of thermal burns admitted to Harlem Hospital since Feb. 1, 1943 and 1 case of severe burns admitted to the Babies Hospital have been treated according to this procedure. There was no selection of cases; 12 additional cases of partial thickness (second degree) burns are omitted from this report. Certain data relating to the patients with full thickness (third degree) burns who have been treated are summarized in table 1. Figure 1 indicates the location of the third degree, full thickness burns and the areas that were skin grafted¹⁹ in certain cases. The following typical cases illustrate the course of events:

W. R., a man aged 43, was admitted to Harlem Hospital at 1:35 a. m. just after having been burned by fire while asleep. The chest, anterior abdominal wall, left side, entire back, left axilla and left arm and right buttock presented the hard, brawny edema with lifeless skin characteristic of third degree burns and constituted 35 per cent of the body surface (W. R. in figure 1). All these areas required skin grafting. The neck, left forearm and hand and left buttock were blistered and showed deep second degree burns. These areas healed without grafting. Relevant data are summarized in figures 2 and 3. Blood pressure, 70 systolic, 50 diastolic on admission, remained low for eight hours, then increased to normal range.²⁰

B. S., a girl aged 8 years, was admitted to the Babies Hospital at 9 p. m. just after having set fire to her clothing while playing with matches. The right side of her chest, both upper arms, the right axilla, the back from the neck to the buttocks and involving the right buttock, the right thigh and part of the right leg were burned. There were few blisters; the full thick-

Fig 3—Sodium and chloride balance in aforementioned case. Horizontal axis, time after the burn; vertical axis, quantity of sodium or chloride in milliequivalents. The sodium intake in the form of lactate is shown by the area in the box with interrupted lines. The sodium excretion is much less than the intake. The deficit on the fourth day exceeds 1,000 milliequivalents of sodium; note the increased excretion of sodium (after therapy had ceased) on the eighth and ninth days. The chloride excretion is seen to be much less than the intake of sodium chloride (indicated by the interrupted horizontal line) until after the sixteenth day, when the output approaches normal.

ness (third degree burn) appeared to involve approximately 22 per cent of the body surface. The relevant data of this case are summarized in figures 4 and 5.²⁰

These results illustrate the rising hematocrit reaching the peak of 58 to 60 per cent from four to approximately twenty hours after the burn, and the steady decline in chloride²¹ and proteins. The "shock" blood pressure approached normal while the hematocrit was still high; the "hemoconcentration" was actually a

Fig 4.—Changes in severe burn case treated with oral sodium lactate (B. S.) (weight, 26 Kg.). The areas with sloping lines indicate the average normal range. The amount of sodium retained is shown at intervals at the top of the chart (amount vomited was subtracted). The plasma protein concentration dropped but subsequently increased without administration of plasma. The pH was computed from the carbon dioxide measurements on arterial blood by using the Henderson-Hasselbalch equation $pH = 6.1 + \log \frac{HCO_3^-}{H_2CO_3}$. The values for carbon dioxide content were obtained on whole arterial blood for experimental reasons²² and are not directly relevant in this study. The carbon dioxide combining capacity was computed by alignment charts and is graphed with the normal range indicated by the shaded area. There was an initial uncompensated acidosis corrected by sodium lactate therapy. The slight alkalosis that followed was of the compensated type. The plasma sodium was low on admission (133 milliequivalents per liter) and decreased to 129 milliequivalents per liter on the third day. On the fifth and ninth days the plasma sodium was 130 milliequivalents per liter and on the eleventh day it was normal at 145 milliequivalents per liter.

decrease in the concentration of plasma proteins and chlorides accompanied by increased relative erythrocyte volume. There was comparatively little surface oozing although the brawny edema was prominent and extensive. (It is not yet possible to assess the relative benefit of this systemic therapy and the neutralized [pH 7.6] tannate-ionized sulfadiazine ointment in preventing loss of fluid from the surface. The local treatment of patient B. S. was a sulfathiazole emulsion; the oozing was much less than had previously been noted in similar cases treated with plasma.) It is significant that the right hand and arm of W. R. and the left thigh and leg of B. S.—not burned—at no time showed any edema despite the ingestion of large volumes of isotonic fluid and the transient low plasma protein concentrations of 4.2 Gm. per hundred cubic centimeters. It is of further interest that these low levels on the second day steadily increased to the normal range without administration of any plasma.

21. The decline in chloride undoubtedly was due at least in part to the large amount of lactate given. Sodium determinations in case B. S. and other cases have shown that there is at least a pronounced fall in the sodium concentration of the plasma despite the large amount of sodium administered.

19 Fox, C. L., Jr., and Tamerin, J. A.: The Use of Soluble Sulfonamides in Extensive Third Degree Burns, *Bull. New York Acad. Med.* 19: 669 (Sept.) 1943.

20 The data are also tabulated in the author's reprints.

In general, the large volumes of fluid were well tolerated; the patients wanted water to drink but after a short time became accustomed to the lactate and drank copiously of their own volition. Occasionally, frequent vomiting occurred and was treated by passing a Levine tube and administering the lactate by steady drip. When the initial vomiting persisted, intravenous infusion was used temporarily to support the circulation until the stomach became adjusted to receiving the steady flow of sodium lactate. (For the temporary infusion in emergencies, sterile saline solution may be used if sterile one-sixth molar sodium lactate is not immediately available.) It is possible that a smaller volume of isotonic fluid is actually necessary, but in the present state of knowledge, until urine secretion begins, it is difficult to gage the amount to give. Since Rosenthal⁹ found hypertonic solutions less effective than isotonic, capsules of salt followed by water were not used.

Fig. 5.—The intake of sodium ion is shown by the height of the interrupted lines (the width on the first day is narrowed to indicate the shorter time interval from admission at 9 p. m. to 7 a. m.). At the end of the fourth day the sodium intake exceeded the sodium output by over 800 milliequivalents. The chloride excretion, which approached normal by the sixteenth day, was far below the average daily intake of 100 milliequivalents. The brief duration of oliguria is shown. The diuresis on the sixth to eighth days coincided with the disappearance of edema in the burned regions.

It is also worthy of note that in these cases copious urinary output occurred from six to twelve hours after therapy was begun. Albuminuria did not occur. Furthermore, the nonprotein nitrogen values in the blood did not become elevated. This is in pronounced contrast to the oliguria, albuminuria and azotemia characteristic of burns treated by other methods.¹

COMMENT

Owing to the fact that from one to eight skin grafting operations²² were required in these cases, the extent of full thickness burns could be definitely ascertained. The results in these severe burns constitute *prima facie*

evidence of the therapeutic efficacy of large amounts of oral sodium lactate instead of intravenous plasma.

The biochemical changes involved have only begun to be studied. In a preliminary abstract, Wilson and his collaborators²³ noted that the sodium in the blood plasma in the veins leaving burned areas was lower than the sodium concentration of the inflowing blood plasma. Scudder has emphasized the need for large doses of sodium chloride to combat the rise in the plasma potassium concentration which he noted occurred early in burns.²⁴ Harkins¹ reproduced data from Wilson's clinical papers which show definite reduction in blood chlorides but withheld comment. Rosenthal's experiments⁹ bring the significance of disturbance in sodium/potassium balance into sharp focus, and the present clinical data give some indication of the magnitude of the disturbance.

As seen in figures 3 and 5, despite copious urinary output the huge quantity of sodium and fluid administered was not promptly excreted but was retained in the body and gradually appeared in the urine over a ten to twenty day interval. In other words, there was distributed within these patients a volume of fluid isotonic with respect to sodium which represented approximately three fourths or more of their normal volume of extracellular fluid (plasma plus interstitial fluid).²⁵ Similar findings were noted in the other cases of extensive burns.

In addition, Davidson's observations on the disappearance of the chlorides from the urine¹² were strikingly confirmed. It is for this reason that 1 case of second degree burns is cited (last case, table 1), because there too the plasma chlorides dropped significantly and the urinary chlorides fell to zero and remained depressed for ten days after the burn.

Further studies of the redistribution of sodium are in progress. It is, however, pertinent to mention here that experiments on the distribution of radioactive sodium administered to shocked animals revealed that enormous quantities of sodium entered the injured muscle and skin.²⁶ Normally skin contains little sodium, and muscle considerably less.²⁷ The depletion of the blood of sodium by the injured tissues has been suggested²⁶ as the chief cause of the "deficit in blood volume" recently described as "the anatomical factor immediately responsible for circulatory failure" in all types of shock.²⁸

Extension of these studies may answer the important question as to whether a judicious combination of small amounts of plasma with sodium lactate might be more effective than sodium lactate alone. Plasma can supply protein as well as salt, but the amount of plasma required to supply the necessary sodium would exceed 10,000 cc., an amount not readily administered intravenously. The function of plasma is twofold: to augment the effective circulating blood volume and to increase the concentration, and hence the osmotic pressure, of

22. The numerous skin grafting operations in these cases were carried out by Dr. Joseph A. Tamerin, with the assistance of Dr. Samuel C. McKinney and Dr. Arthur Garnes, by a technic described elsewhere (Whipple, G. H.: *Basic Principles in the Treatment of Thermal Burns*, *Ann. Surg.* **118**: 187 [Aug.] 1943; discussion, p. 192. Fox and Tamerin.¹).

plasma proteins. How permanently therapy with large amounts of plasma alone accomplishes these ends needs further study; this need is suggested by the previously mentioned observations of Scudder and Elliott,⁷ of Rhoads, Wolff and Lee⁸ and of Elman⁹ together with the recent experiments of Fine, Seligman and Frank²⁹ using radioactive plasma. It appears plausible from our results that by greatly increasing the volume of interstitial fluid the diminished plasma volumes in shock can be restored. For example in case B. S. the low initial plasma volume of 720 cc was raised to the normal range (1,170 cc.) by this therapy without plasma. In addition, more accurate evaluation of the actual loss or withdrawal of plasma proteins from the

Whatever may be the ultimate conclusion about the added benefit of small amounts of plasma, the fact that extensively and severely burned patients survived and recovered after the oral administration of isotonic sodium lactate instead of the intravenous injection of plasma proves that correction of the sodium imbalance is of major importance. W. H. and S. M. were the first patients treated. As experience had not yet justified full confidence in the method, each received 200 cc. of plasma. There is no reason to believe that this small amount of plasma contributed to the favorable outcome. No plasma was used in any of the other cases.

The simplification in the care of such patients is worth noting. Intravenous therapy is dispensed with

TABLE 1—Summary of Third Degree Burns* Treated Initially with Oral Sodium Lactate Instead of Plasma

Case, Sex, Age	Area Third Degree Burn Percentage by Berkay Scale	Laboratory Data	First Skin Graft (Days After Burn)
W R ♂ 40	Chest, abdomen, entire left side, left arm including axilla, back, right flank, both buttocks 56%	Hematocrit 60% on 2d day; total protein 42 Gm per 100 cc and chlorides 76 mEq 2d day. see table 2 for complete details	First operation on 45th day; 2d operation on 62d day; six additional operations to resurface completely; discharged healed on 153d day
W H. ♂ 0	Entire right arm, forearm, fingers (olecranon process and flexor tendons at wrist exposed), chest, abdomen, inner aspect of both thighs and groins, penis (circumcised by burn), upper part of scrotum a continuous burn; right side and flank, 41%	Hematocrit 51% on 3d day, chlorides 89 mEq on 3d day, total protein 65 on admission to 47 Gm per 100 cc on 3d day	First skin graft 39th day; four subsequent operations, discharged on 112th day, healed
S M ♀ 7	Right arm, left arm, upper forearm, both thighs lower chest, abdomen, right flank, side of chest, right lower back, 34%	Hemoglobin 118% 2d day; chloride 69 mEq on 10th day; total protein to 52 Gm per 100 cc on 5th day	First skin graft 44th day; three subsequent operations; discharged 136 days, healed
B S ♀ 8	This case treated at the Babies Hospital, New York. Entire back, both upper arms, right axilla and right chest, left buttock, right thigh 4%	Hematocrit 59%; plasma proteins dropped to 42 Gm per 100 cc and chlorides to 83 mEq, plasma volume 720 cc on 1st day increased to 1,170 cc after therapy; see table 3 for complete details	5% sulfathiazole emulsion used, surface oozing through dressings less than in similar cases treated with plasma; dermatone grafts placed in four operations, discharged healed on 86th day
M H ♀ 37	Left arm, forearm, hand and fingers (except palm); left side and axilla, both legs, both outer thighs and buttocks, 32%	Hematocrit 30% on 1st day to 38% on 4th day, chlorides 85 mEq on 3d day	First skin graft 24th day; died 13 days postoperatively, 35 days after admission; hematuria, hypernephroma?
G J ♀ 5	Left arm, axilla, left half of chest and abdomen, left half of back to midline, 24%	Total protein to 525 Gm per 100 cc; chlorides 9, mEq on 2d day	First skin graft on 31st day; two additional operations; healing on 75th day
A G ♀ 30	Both buttocks, both thighs, left leg third degree areas on both thighs and legs, 19%	Hematocrit 547%; plasma chlorides dropped to 87 mEq, urine chlorides 0.14 Gm in 24 hrs	Patient refused grafting operation, granulations healing slowly at 2 mos still in hospital
M B ♀ 1	Face, all extremities, thorax, abdomen and back: 80%; pulmonary edema	Admission values normal	Admitted in pulmonary edema with carbon monoxide poisoning; died in 4 hours
C G ♂ 29	Case with second degree burns only. Left arm, shoulder, upper half of back. All deep second degree burns; 16%; this case is included because of pronounced shock, blood pressure 90/50 and opportunity for complete blood studies	Hematocrit to 51% 2d day; total protein dropped from 66 (adm) to 61 on 3d day, chlorides dropped from 112 mEq (adm) to 89 mEq on 4th day with no chloride in urine	No grafts needed; discharged on 17th day, healed

The percentages refer to third degree area only (except C. G. above). It is of interest to compare these cases (9 additional cases appear in the author's reprints) with the not dissimilar group of 10 burn cases which required skin grafting following the Coconut Grove fire.⁴ The burns in this group including first and second degree areas were reported to range from 85 to 56% of body surface. A total of 63 units of plasma was used in the first 3 days for the 10 patients. Since this table was compiled, 6 additional patients with extensive full thickness (third degree) burns and 3 patients with some partial thickness burns have been treated with sodium lactate. All recovered from shock and showed the typical blood and urine changes described.

circulation is essential. It is possible that in our cases external plasma loss was reduced by the neutralized tannate ionized sulfadiazine ointment applied locally¹⁴ without pressure bandages. The recent studies of Drinker,³⁰ however, have demonstrated the high protein content of the increased quantity of lymph obtained by cannulating lymph ducts draining burned extremities. It is possible that plasma proteins not actually lost from the surface may be returned relatively soon to the blood stream via the lymph channels, particularly in view of the delayed clotting when no pressure is used.³¹ (Comparative observations indicate substantially greater surface loss of plasma in plasma treated cases than in sodium lactate treated cases.)

and the medical staff and nurses are relieved of this burden. The sodium lactate costs but a few cents and the hospital supplies of blood and plasma are conserved. The problems of sterile solutions are eliminated.

It is scarcely necessary to mention the military advantages of the simplification of shock therapy that would follow conclusive demonstration of the efficacy of this treatment of burn shock.³² For the present at least, the emergency use of this method under circumstances in which plasma is not immediately available seems clearly indicated.

This preliminary report will be followed by a more detailed report in which studies of the circulation by the shock group²⁸ will be combined with measurements

³² Rosenthal⁴ has recently developed a technic for the experimental production of uniformly fatal traumatic shock by means of tourniquets. Therapeutically isotonic solutions of sodium salts were more effective than equal volumes of plasma. Plasma was slightly more effective by mouth than by vein. Similar experiments with radioactive sodium in this type of shock showed the enormous deposit of sodium in traumatized tissues,² analogous to the redistribution following thermal burns but quantitatively of greater magnitude.

would appear to be adequate quantities of dextrose. In no instance except one was there spontaneous remission of the attacks. In this exceptional case (Gray⁶) attacks subsided after removal of the pancreatic tumor where hepatic metastases were present. This patient received large amounts of dextrose postoperatively but died six weeks after excision, and the cause of death was not clearly apparent. Since some islet cell carcinomas have been observed not associated with hyperinsulinism, a plausible explanation for the situation is that only the cells of the primary growth retained insulin producing properties, whereas the metastatic growths did not retain these properties.

The evidence for symptomatic improvement in the case cited in detail is as follows: Attacks of hyperinsulinism recurred after exploratory laparotomy and biopsy had revealed hepatic metastases of the previously

therefore have been predicted on the basis of the animal studies that a series of injections in this case would have resulted in temporary improvement with return of attacks. This, as stated, is what did occur.

Two other features of the case deserve special mention: 1. As a result of repeated attacks of hyperinsulinism a tolerance to low blood sugar levels developed. The patient was able to conduct himself normally with blood sugars as low as 20 mg. per hundred cubic centimeters. His "attack level" was 14 mg. per hundred cubic centimeters or less. 2. Forced ingestion of food in an attempt to ward off attacks resulted in a 35 pound (16 Kg.) weight gain over a period of seven months after carcinomatosis of the liver was observed at laparotomy. This would indicate that "carcinoma cachexia" is merely the result of gradual reduction in caloric intake and not due to a "toxemia" originating from the tumor cells. Thus successful forced nutrition in some cancer patients should prove to be of palliative value. As already indicated, man appears much more resistant to the action of alloxan than the rabbit or the dog. Furthermore, in man no evidence of injury to the convoluted tubules of the kidney was observed, whereas in animals this was a frequent finding.

Injury of the insulin producing system of an islet cell in itself does not signify that the cell as a whole might be fatally injured, in that it might well be possible to inhibit insulin production while the cells continue to survive and to proliferate. Studies in animals would suggest that the cell itself as well as the insulin producing mechanism is injured by alloxan. However, in the case reported the normal and neoplastic islet cells were not necrosed but there was temporary inhibition of insulin production. How significant this substance may prove to be in the symptomatic and palliative treatment of one specific type of cancer (insulin producing islet cell carcinoma) can be demonstrated only after further trial and more prolonged observations. Temporary relief from attacks of hypoglycemia in itself would constitute effective palliation. Alloxan might afford beneficial effects, at least temporary, in those patients with recurring hyperinsulinism after operation at which an islet cell adenoma is not found and pancreatic tissue is removed without lasting benefit.

SUMMARY

1. Alloxan, the ureide of mesoxalic acid, also a component of the uric acid molecule, has been observed to produce specific necrosis of the islets of Langerhans in the rabbit and dog with resultant hyperglycemia. Similar histologic effects were not observed in patients receiving larger doses.

2. Alloxan was administered as a chemotherapeutic agent to a patient with insulin producing islet cell carcinoma, metastatic to the liver, who presented recurring attacks of hyperinsulinism increasing in frequency and severity. The rationale for this was that, since the radiosensitivity of tumors roughly parallels the radiosensitivity of the normal tissues from which they arise, a chemical agent exerting specific noxious effects on normal pancreatic islet cells might influence favorably insulin producing islet cell carcinoma.

3. Temporary symptomatic relief was obtained in that the attacks were obviated for brief periods following each series of injections. Death resulted from a complication at laparotomy. Alloxan did not cause necrosis of the malignant islet cells.

removed islet cell carcinoma with no evidence of neoplasm in the remaining pancreas; hence the metastases produced insulin. Over a period of several months attacks developed with progressive increase in frequency and severity, finally occurring at the rate of two to five a day. It was apparent that there was increasing difficulty in obtaining recovery from attacks by ingestion and injection of dextrose. The frequency and severity of attacks was definitely diminished following injection of alloxan. Periods of several days (as long as three weeks) occurred without attacks. Improvement in the situation occurred in the face of substantial curtailment of ingestion of food. Fasting blood sugar levels became elevated as compared with preinjection determinations. Finally, improvement followed injections with recurrence of attacks after a period, and subsequent improvement occurred after repetition of the injections. Studies on dogs revealed that whereas some islet cells were injured, resulting in a diabetic state, the majority were not destroyed or much affected and recovery ensued with return to normal blood sugar levels. It might

CLINICAL EXPERIENCES WITH
DICUMAROL

REPORT OF EIGHTEEN CASES

LIEUTENANT (jg) HOWARD D. ZUCKER
(MC) U.S.N.R.

The early favorable reports¹ on the use of the new synthetic orally administered anticoagulant dicumarol² have led me, during recent months, to a trial of the drug in 18 cases at the Lenox Hill Hospital. Opinions drawn from the use of any drug in such a small series are necessarily of limited value, but I feel that a report of the observations may be of some assistance in the evaluation of a drug which has variously been branded as useless or as excessively dangerous in effective dosage³ and, on the other hand, as of great value in the prevention of pulmonary embolism.⁴

SELECTION OF PATIENTS

Of the 18 patients treated, the largest group, 9, were suffering from clinically evident thrombophlebitis of the lower extremities. Five patients received prophylactic doses of dicumarol, following operation or delivery, because of a history of previous episodes of thrombosis or embolism. Two patients were treated subsequent to a postoperative pulmonary infarction. One patient was treated following a cavernous sinus thrombosis, and 1 was treated when cavernous sinus thrombosis seemed imminent. No patients with definite evidence of liver damage or with definite renal impairment were accepted for treatment because of the experimental evidence that such damage is a contraindication to the use of dicumarol.⁵

DOSAGE AND CONTROL

All patients were classified according to blood group prior to therapy, and all had daily determinations of the plasma prothrombin level (except on Sundays) performed in the hospital laboratory on undiluted plasma by the Quick method. In addition, hemoglobin determinations and red blood counts were performed every second day. Microscopic urinalyses were frequently performed in search for red cells, and physical examinations of the patients were performed daily, including arterial blood pressure determinations.

All adult patients received an initial dose of 300 mg. of dicumarol by mouth, and the following morning, regardless of the time of administration of the initial dose, an additional 200 mg. was given. Subsequent doses were given with the aim of maintaining the plasma prothrombin time level between 60 and 30 per cent of

normal in accordance with the experiences of Allen, Barker and Waugh.⁶ With this range in mind the usual follow-up doses were 200 mg., and administration of such doses depended both on the absolute level of the daily prothrombin determination and on the slope of the plotted curve of prothrombin values.⁷ The significance of the slope of the curve must be stressed, for the prothrombin time may be excessively and dangerously lengthened if a follow-up dose is given while the slope of the curve is upward (decreasing percentage of normal), and conversely the patient may escape from the desired range if one waits for the return of the prothrombin time to a specified level rather than administering the follow-up dose as soon as a definite swing to normal (4 per cent, or 5 seconds) is noted in the curve. No limit was set on the total amount of drug to be administered to any patient.

Despite the recognized fact⁸ that some persons are highly resistant to dicumarol (3 in our series) and others are remarkably susceptible (also 3 in our series) a program of dosage such as has been outlined permits maintenance of the majority of patients within the desired range of hypoprothrombinemia. It is necessary to administer follow-up doses of 300 mg. or more to patients recognized to be resistant, and reduction to

Chart 1.—Light broken line, prothrombin curve of Mrs. G. Note failure to heed 4 per cent drop in prothrombin time on tenth day with subsequent escape from therapeutic range. Heavy solid line, prothrombin curve of Mrs. H. (patient 1). Note slight overdosage on second day, escape on sixth day due to disregard of drop in curve, and proper method of dosage on eleventh and twelfth days. (See text.)

100 mg. is occasionally necessary in susceptible persons. Once therapeutic levels had been obtained, 7 of our last 10 patients treated according to the aforementioned principles were maintained at all times within the range of 62 to 30 per cent. Three cases were not entirely satisfactory, and of these 2 escaped above 62 per cent for one determination only, while the third escaped for a three day period. Chart 1 demonstrates the principles of dosage which have been discussed. In addition to dicumarol each patient received such drugs and treatments as were prescribed by the internist or surgeon in attendance. Thus sulfadiazine was given to 7 patients, and ice bags were applied intermittently over the affected region in the cases of thrombophlebitis. The patients with thrombophlebitis were given active foot exercises as soon as a therapeutic hypoprothrombinemia had been recorded.

From the various services of Lenox Hill Hospital.
Dr. Zucker was one time house physician and resident roentgenologist, Lenox Hill Hospital.

This study was carried out under the guidance and encouragement of Dr. Carl Eggers, attending surgeon. The cases were made available for study through the active cooperation of many members of the attending and house staffs, including particularly Dr. Mortimer W. Rodgers, associate attending gynecologist and obstetrician.

RESULTS OF TREATMENT

(a) *Thrombophlebitis*.—All of the 9 patients who received dicumarol while suffering from thrombophlebitis recovered. No suggestion of embolization was observed during the course of any of these cases; this observation is in no way remarkable, since embolization during the course of clinically recognized thrombophlebitis is infrequent. The recovery of 1 of these patients can in no way be related to dicumarol therapy, since no adequate prolongation of the prothrombin time was achieved (below 62 per cent for only two days).

The average duration of dicumarol therapy in these cases was fourteen days, and the longest treatment lasted sixteen days (exception is case 1). Hospitalization, as a rule, was continued for a few days after the prothrombin time had been permitted to return to normal. It is my opinion that the duration of the illness in these cases, many of which were severe, was shorter than would have been expected without the use of dicumarol.

In the entire group there was no evidence of central extension of the thrombus once an adequate prothrombin time had been reached, although in several cases peripheral extension continued for several days.

Disappearance of pain in the affected area or pronounced diminution was observed in 7 of the cases at the time when the desired level of hypoprothrombinemia had been reached. This pain diminution persisted in contrast to the analgesic effect of ice packs, which usually lasted only a few minutes after the pack was removed and which often was unsatisfactory over long periods of time. In 1 case in which the prothrombin time escaped to normal levels the pain recurred coincident with the escape and disappeared again as control was reestablished. In another case there was a delay in establishing hypoprothrombinemia because of resistance to the drug, and the pain disappeared only when the dicumarol was finally effective in lengthening the prothrombin time.

One case of interest is presented:

CASE 1.—Mrs. H., aged 59, a housewife, was admitted on March 29, 1943 for pain, swelling and redness of the right lower extremity. There was a history of right sided thrombophlebitis one and one-half years previously, and the patient had bilateral varicose veins of long standing. Oscillometric readings showed poor arterial circulation in both lower extremities. There was an increase in signs and symptoms despite bed rest, ice packs and elevation. On April 7 dicumarol therapy was instituted and the pain and tenderness in the right thigh rapidly disappeared, although the edema persisted for two weeks. The prothrombin time was permitted to return to normal after nineteen days of treatment (April 25) and the patient was allowed up.

On May 1, six days after treatment had been discontinued, the patient complained of heaviness and pain in the left popliteal region, and an abnormal cordlike structure could be felt there. The next day tenderness in the femoral region was also encountered. Dicumarol therapy was reinstated on May 1, and a satisfactory prothrombin level was reached on May 3. The pain and tenderness rapidly disappeared and no further extension of the process was noted. On May 11 the prothrombin time was permitted to return to normal range and the patient was permitted to hang her feet out of bed on May 12 and to get up on May 15.

There was some elevation of temperature on May 16, five days after dicumarol therapy had been discontinued, and the patient began to complain of pain in the left thigh. On May 21 a firm pencil-like mass was palpable in the left thigh on its medial aspect. Dicumarol was once again started on May 24, and a therapeutic level had been reached on May 25. The

patient was now "fairly comfortable," according to the nurse's notes. She experienced a little pain the following day but then remained entirely comfortable until June 1, when she complained of a brief spasm of pain. On June 7 she complained of pain most of the day, and it was found that for the first time she had escaped from a therapeutic range of hypoprothrombinemia. Within thirty-six hours a satisfactory level had been restored and the pain had disappeared. Improvement has been progressive since and the patient (June 20) is up and about, still on dicumarol.

The sequence of events in this case is strong evidence that dicumarol may favorably modify the course of thrombophlebitis. Coincidence would seem an inadequate explanation for the relationship of dicumarol therapy to this series of remissions and relapses.

(b) *Prophylaxis*.—Five patients were given postoperative courses of dicumarol; of these 2 had undergone general surgical procedures, 2 had been delivered by cesarean section and 1 had undergone sterilization and therapeutic curettage. Four of these patients had a history of one or more antecedent episodes of thrombosis, and 1 of these had had a pulmonary infarct. All the patients in this group had uncomplicated postoperative courses. The longest postoperative hospitalization was fifteen days.

A representative case from this group is presented:

CASE 2.—Mrs. M. M. was admitted in the third month of her first pregnancy. Four years previously she had an extensive thrombophlebitis of the left leg, which was first noted on the twelfth day after appendectomy; she was hospitalized for seventeen days thereafter and has since been subject to swelling of the left leg. One sister died of a pulmonary embolus secondary to a postpartum thrombophlebitis, and a second sister underwent amputation of her left lower extremity when a thrombosis developed after childbirth.

On May 23 sterilization and therapeutic curettage were performed and on May 26 a prophylactic course of dicumarol was started. The prothrombin time was maintained within the therapeutic range until the patient was discharged well on her eleventh postoperative day.

(c) *Pulmonary Embolism*.—Two patients who suffered postoperative emboli were given courses of dicumarol in the hope of inhibiting further thrombosis and embolization. Neither patient had any evidence of further embolic phenomena and both had uncomplicated recoveries. One of these patients had a thrombophlebitis of the superficial veins of her left thigh, and the local pain of which she complained disappeared at about the time that her prothrombin time reached the desired range. The other case is reported in greater detail:

CASE 3.—Mrs. S. S., aged 42, a housewife, entered the hospital the second time for vaginal bleeding secondary to adenomyosis uteri. Preoperative examination of the lower extremities was negative. An uneventful supracervical hysterectomy was performed on March 2, 1943. On March 5 the patient experienced sudden right chest pain, accentuated on inspiration and accompanied by small amounts of blood flecked sputum. The chest pain continued for several days, and a friction rub was heard on three occasions. Physical examination on March 8 revealed slight but definite tenderness on the lateral aspect of the left calf, and dicumarol was started. An effective hypoprothrombinemia was maintained from March 9 to March 15, but despite the anticoagulant therapy a superficial thrombophlebitis developed in the right antecubital fossa secondary to a venipuncture, and this process spread several centimeters centrally and peripherally during the following two days. The tenderness in the left calf rapidly disappeared, but the antecubital region remained tender and painful for several days. The remainder of the patient's course was uncomplicated and she was discharged well on April 4, 1943.

(d) Cavernous Sinus Thrombosis.—

CASE 4.—W. L., a man, was admitted on May 25 for massive nasal and facial swelling associated with right orbital cellulitis and proptosis, and with thrombosis of the right retinal veins. Blood culture was positive for *Staphylococcus aureus*, and sulfadiazine was immediately started. The patient's clinical course was downhill, and all observers agreed that he had a right cavernous sinus thrombosis. Dicumarol therapy was instituted and on May 30 an effective level was reached; on that day, for the first time, the patient seemed somewhat improved. He improved rapidly for several days and gradually thereafter; the temperature began to subside on May 30. A therapeutic hypoprothrombinemia was maintained until June 16, and the patient was discharged on June 17 well except for right amblyopia. This course is presented in chart 2.

CASE 5.—J. C., a boy aged 12 years, treated for imminent cavernous sinus thrombosis, was admitted for massive facial swelling and tenderness secondary to pericementitis of a left upper central incisor. There was localized tenderness over the lateral (left) nasal vein. Sulfadiazine was started, and on May 12 the affected tooth was removed; postoperatively dicumarol therapy was begun. No improvement was noted during the following day, but that night (May 13) the desired

Chart 2 (case 4).—Light solid line, prothrombin time. Broken line with black dots, fever curve.

hypoprothrombinemia was achieved and on the following morning improvement in the facial swelling and tenderness was noted, which continued until the patient was discharged much improved on May 22.

The pain pattern is worth noting; on May 12 the notes state that the patient was "crying, irritable" and the same note is made the following morning; that afternoon he was "crying, depressed," but that night he "seemed more contented" and thereafter each note stated that he was comfortable. Again relief from pain and satisfactory hypoprothrombinemia correlate.

TOXICITY

One of our 18 patients developed a petechial rash on the fifth day of treatment, at which time his prothrombin time had dropped to 18 per cent of normal (considerably lower than our desired range of 30 to 62 per cent). The petechiae were distributed over both shoulders and both flanks. No conjunctival, sublingual or retinal hemorrhages were present, but a Rumpel-Leede test was moderately positive. On the same day 25 to 30 red blood corpuscles per high power field were observed in a centrifuged urine specimen. The rash

disappeared over a period of about four days, while the Rumpel-Leede test became negative after three days. Microscopic hematuria continued for eight days, reaching its maximum of 40 to 50 red blood corpuscles per high power field on the fourth day of the episode. The patient had an otherwise uneventful recovery; a more detailed discussion is presented in the report of case 4. Chart 2 shows the prothrombin curve in this case.

None of the remaining patients showed any evidences of macroscopic hemorrhage, although 3 of them had prothrombin times of 22 per cent or less on one or more occasions. It should be noted that this included 11 post-operative patients, none of whom developed hematomas, and 4 postpartum patients, none of whom bled or had abnormal lochia.

Microscopic hematuria was found in 4 cases other than the 1 reported. The prothrombin time was 30 per cent of normal or less in 3 of these at the time when the red cells appeared. In each case the urine quickly cleared. We have excluded from this group 10 patients who showed microscopic hematuria following operations in the genitourinary regions but have included a patient whose urine cleared following supracervical hysterectomy and subsequently showed red cells (thirteenth postoperative day).

Three patients have complained of nausea following a dose of dicumarol. The drug was continued in each case, and in none did the nausea recur. Despite a careful search, no other possible evidences of dicumarol toxicity were found; there was no suspicion of liver damage and no evidence of embolization. The danger of hemorrhage following venipuncture has been mentioned by others;⁸ I have seen no instances of this complication, although the only precaution has been the use of a fine (23 or 24 gage) needle.

COMMENT

Dicumarol has been criticized from the point of view of difficulty of control.⁹ My experience confirms the difficulty of ideal control, but I feel that the majority of patients can be maintained within desired prothrombin time limits if the frequency and size of follow-up doses is modified according to the slope of the prothrombin curve and the response to the initial three doses, as well as according to the absolute level. With such a program the few patients who escape from control will be suffering from underdosage rather than overdosage, and toxic manifestations (hemorrhage) will be unlikely.

Critics have stressed the danger of hemorrhage with dicumarol therapy¹⁰ and have suggested the possibility of other toxicity.⁹ To date no clinical or experimental evidence in the literature has shown toxicity other than hemorrhage; my experiences are in agreement with this fact. In this small series no hematomas or hemorrhages were observed; 1 patient had a mild transient purpura, and 4 other patients showed transient microscopic hematuria. I feel that chance may in part account for the absence of hemorrhage in this series but suggest that the method of dosage may be in part responsible. The lack of significant toxicity under proper control is in agreement with the impression of Wright^{10a} that dicumarol may be safer for general use than heparin.

10a. Wright, I. S.: Thrombosis: Modern Concepts of Cardiovascular Disease, published by American Heart Association 12, No. 4, 1943.

The results of treatment with dicumarol, as with any new drug, are difficult to assay. I was impressed with the rapid recovery and short convalescence of 8 of the patients treated for thrombophlebitis; dicumarol may well have expedited their recovery. In addition, the disappearance of pain in 7 of these patients and in 2 from other groups seemed to parallel the achievement of therapeutic levels of hypoprothrombinemia. I have found no other mention of this phenomenon in the literature. If the disappearance of pain in thrombophlebitis were due to hypoprothrombinemia, one might postulate that the pain was secondary to the venospasm resulting from the propagation of a thrombus; when the propagation has been stopped the pain disappears.

The prophylactic results, the results in cavernous sinus thrombosis and in threatened cavernous sinus thrombosis and the results in 2 cases of pulmonary embolism are interesting, but no further comment seems justified in such a small series. The excellent results reported from the Mayo Clinic⁴ are of particular importance in the last regard.

Of considerable theoretical interest was the development of thrombophlebitis in 1 of the patients while under adequate dicumarol therapy (patient 3). This raises the question as to whether dicumarol hypoprothrombinemia of the magnitude produced in this series is sufficient to inhibit intravascular clotting. Although the experiments of Bollman and Preston,⁵ Dale and Jaques¹¹ and Richards and Cortell¹² demonstrate inhibition of clotting in the presence of dicumarol hypoprothrombinemia, these experimental results do not seem comparable to human conditions because of the severity of the hypoprothrombinemia induced in most experiments and because of the relatively drastic alterations in the condition of the vessel walls. Davidson and McDonald⁹ felt that massive and dangerous dosage was necessary to produce adequate changes in coagulability, but in my opinion their experiences with the coagulation time in lusteroid tubes does not necessarily lead to this conclusion. In any event the available experimental evidence is inadequate to determine whether dicumarol, in the stated range, is able to prevent thrombosis in human veins under conditions of stasis and clot propagation. I believe that dicumarol is effective and that the development of thrombophlebitis in the case under discussion illustrates a safety factor in its use. It is hypothesized that hypoprothrombinemia in the 60 to 30 per cent range is sufficient to inhibit purely venostatic coagulation, whereas coagulation of the hemostatic type associated with the local accumulation of thrombokinase may occur.

CONCLUSIONS AND SUMMARY

1. Dicumarol was administered orally to 18 patients with various indications. All the patients had uncomplicated recoveries; this includes 1 case of cavernous sinus thrombosis.

2. One patient had a transient purpura, and 4 other patients had transient microscopic hematuria. No other evidences of hemorrhage were observed although 11 postoperative and 4 postpartum patients were treated. No evidence of toxicity other than hemorrhage was observed.

3. Control of the prothrombin level during dicumarol therapy is not easy, but the method of dosage which

I have used has proved generally effective and invariably safe in a small series.

4. Dicumarol seems to have a beneficial effect in cases of thrombosis and embolism. No more definite statement can be made until many more cases have been reported. In this series the disappearance of pain and the achievement of hypoprothrombinemia showed a striking relationship.

5. Dicumarol cannot, in my opinion, replace heparin in emergencies demanding anticoagulant therapy, nor should it be used as an alternative to indicated surgical procedures.

6. The cheapness of dicumarol, its ease of administration, its apparent margin of safety and its possible efficacy in thrombotic diseases warrant further controlled clinical trials of the drug. I feel that the ultimate field of usefulness of dicumarol will principally be in the prophylaxis of thrombosis and embolism and in the treatment of thrombophlebitis.

INTRAMUSCULAR ADMINISTRATION OF ANTI-HAEMOPHILUS INFLUENZAE. TYPE B, RABBIT SERUM

A REPORT OF ITS USE IN THREE CASES OF
INFLUENZAL MENINGITIS

PAUL L. BOISVERT, M.D.

MILDRED D. FOUSEK

AND

MARYA F. GROSSMAN, A.B.

NEW HAVEN, CONN.

The development by Alexander¹ of a therapeutic type-specific rabbit serum has dramatically influenced the prognosis in infections by *Haemophilus influenzae*, type b. In our own series of cases of meningitis by this organism, the mortality was 100 per cent (11 out of 11 cases) prior to the use of rabbit serum, and 15 per cent (4 out of 26 cases) with its use in conjunction with sulfonamide compounds. In the past we have administered the serum intravenously or both intravenously and intrathecally as recommended by Alexander.² Recently 3 babies with meningitis due to *H. influenzae*, type b, were admitted to the pediatric isolation wards of the New Haven Hospital and afforded an opportunity for the determination of the effectiveness of the serum when administered intramuscularly.

REPORT OF CASES

CASE 1.—G. K., a boy aged 18 months, was admitted with a history of a "cold" with nasal discharge for one week. During the day before admission he seemed drowsy and in the evening vomited twice. The following morning his temperature was 104 F. By noon the temperature had risen to 106 F. and the family physician noted that the baby's neck was stiff. Hospitalization was advised.

Aided by a grant from the Fluid Research Fund of the Yale University School of Medicine.

On admission to the New Haven Hospital the patient's temperature was 104.8 F.; he was pale, acutely ill, irritable and restless but clear mentally. There was a moderate amount of nasal discharge, and the throat was injected. Both membranae tympani were dull and inflamed. The neck was stiff. Lumbar puncture revealed an initial spinal fluid pressure of 350 mm.

Chart 1 (case 1).—H. Influenzae, type b, meningitis and bacteremia.

The fluid was cloudy and contained 5,200 white blood cells per cubic millimeter, of which 98 per cent were polymorphonuclear leukocytes. Stained smear showed numerous gram-negative, pleomorphic bacilli which were identified by the Neufeld technic of capsular swelling as type b influenzal organisms. Sulfadiazine was administered by mouth in a dosage of $1\frac{1}{2}$ grains (0.1 Gm.) per pound of body weight daily. The contents of three vials of anti-H. influenzae type b rabbit serum, totaling 75 mg. of antibody nitrogen, were injected intramuscularly after negative ophthalmic and cutaneous tests for sensitivity. The baby's temperature returned to normal by the fourth day of hospitalization. On the fifth hospital day his temperature rose to 102.9 F. An excess of free antibody was present, as demonstrated by capsular swelling of the infecting strain of type b influenzal bacillus by the patient's blood serum in a 1:10 dilution. This indicated that an adequate amount of serum had been injected. Fever persisted and a right myringotomy was performed on the following day, although there was no local evidence that an otitis media of a purulent nature was present. Pus was not obtained, and a culture of the auditory canal was

Chart 2 (case 2).—H. Influenzae, type b, meningitis and bacteremia.

negative for the type b influenzal bacillus. The baby's temperature dropped rapidly to normal and convalescence was uncomplicated.

Admission nasal, pharyngeal, spinal fluid and blood cultures were positive for H. influenzae, type b. The spinal fluid sugar prior to treatment was 68 mg. per hundred cubic centimeters. The white blood cell count was 20,500, of which 87 per cent were polymorphonuclear leukocytes. Blood sulfadiazine levels ranged from 9 to 12.9 mg. per hundred cubic centimeters.

An excess of free antibody was demonstrated in the patient's blood eight hours after the injection of rabbit serum and persisted for a period of at least four days as determined by daily tests.

CASE 2.—B. F., a boy aged 20 months, was admitted to the New Haven Hospital with a history of fever up to 105 F. for three days. There were no other signs except anorexia. On the morning of admission he vomited once and appeared drowsy. He was brought to the hospital in the late evening after the occurrence of a generalized convulsion.

The patient's temperature was 102.4 F., the lips were cyanotic and the skin was mottled. Follicular tonsillitis was present. There were occasional convulsive movements of the extremities, and the neck was stiff. Lumbar puncture revealed an initial spinal fluid pressure of 350 mm. The fluid was cloudy and contained 19,000 white blood cells per cubic millimeter, of which 95 per cent were polymorphonuclear leukocytes. Stained smear showed numerous gram-negative pleomorphic bacilli, which were identified as type b influenzal bacilli. Sodium sulfadiazine was administered by infusion and clysis and on the third hospital day was replaced by sulfadiazine orally. The baby's temperature fell to a lower level, but he remained severely ill and influenza bacilli persisted in the spinal fluid. Anti-H. influenzae, type b, rabbit serum containing 75 mg. of antibody nitrogen was injected intramuscularly on the fourth hospital day after ophthalmic and cutaneous tests for sensitivity were found to be

Chart 3 (case 3).—H. influenzae, type b, meningitis and bacteremia.

negative. Fever persisted for the first thirteen days of hospitalization, but there were no complications.

Admission nasal, pharyngeal, spinal fluid and blood cultures were positive for H. influenzae, type b. The spinal fluid sugar before treatment was 33 mg. per hundred cubic centimeters. The white blood cell count was 22,800, of which 87 per cent were polymorphonuclear leukocytes. Blood sulfadiazine levels varied from 12 to 23.6 mg. per hundred cubic centimeters.

An excess of free antibody was demonstrated in the baby's blood twelve hours after the injection of rabbit serum and persisted for a period of at least six days.

CASE 3.—D. M., a boy aged 14 months, was admitted to the New Haven Hospital with a history of fever, anorexia and vomiting beginning on the preceding day. During the night he was restless. On the morning of admission he was examined by the family physician, who noted stiffness of the baby's neck and advised hospitalization. There was a history of a "cold" three weeks previously, which lasted for about ten days.

The patient's temperature was 102.2 F. He appeared acutely ill and was moderately dehydrated. The neck and back were rigid. There were no signs of an upper respiratory infection. Lumbar puncture yielded cloudy spinal fluid, which contained 13,700 white blood cells, all polymorphonuclear leukocytes, and numerous type b influenzal bacilli. One infusion of sodium sulfadiazine was administered; subsequent chemotherapy consisted of sulfadiazine orally. Anti-H. influenzae, type b, rabbit serum containing 75 mg. of antibody nitrogen was injected intramuscularly after sensitivity tests were found to be negative.

The baby's temperature dropped toward normal on the seventh hospital day, and convalescence was uncomplicated except for a transient fever on the ninth day.

Admission nasal, spinal fluid and blood cultures were positive for *H. influenzae*, type b. The spinal fluid sugar before treatment was 16 mg. per hundred cubic centimeters. The white blood cell count was 10,450, of which 69 per cent were polymorphonuclear leukocytes. Blood sulfadiazine levels varied from 4.5 to 13.1 mg. per hundred cubic centimeters.

An excess of free antibody was demonstrated in the patient's blood one hour after the injection of rabbit serum and persisted for a period of at least eight days.

SUMMARY AND CONCLUSIONS

Anti-*H. influenzae*, type b, rabbit serum was administered intramuscularly to 3 babies with meningitis and bacteremia. Chemotherapy consisted of sulfadiazine. An excess of free antibody was demonstrated in the blood of two patients eight and twelve hours respectively after intramuscular administration of the therapeutic serum and was known to persist for a period of four and six days respectively. The exact time of appearance and disappearance of free antibody is not known, since earlier and subsequent tests for its presence were not made. With the third patient, an excess of free antibody was demonstrated in the blood as early as one hour after intramuscular injection of the serum and persisted for at least eight days. Antibody was not present prior to the administration of serum. The 3 babies recovered without sequelae.

We felt justified in administering the serum intramuscularly rather than intravenously, since the first baby was treated early in the disease and was not operately ill. The satisfactory course of this patient to the subsequent use of serum intramuscularly.

The therapeutic serum appears to be effective when administered intramuscularly. Under certain circumstances the technical advantages of intramuscular over intravenous injection of the serum may be significant.³

3. Since this report was written, 2 additional babies have been treated with serum intramuscularly. One, aged 10 months, with laryngitis and bacteremia, recovered without complications; the other, aged 3 months, with meningitis and bacteremia, died. An excess of free antibody was present in the blood five hours and one hour respectively after the administration of serum and was known to persist for nine and sixteen days respectively.

Pericardial Pain.—Exploration of the pericardial sac presented many difficulties. Only patients with a large pericardial effusion were suitable for this method of investigation. After outlining the sac by x-ray, the trocar was inserted first through the intercostal space, then through the pericardial sac, noting the presence or absence of pain during the procedure. Once within the sac, the silver wire was introduced and the point brought in contact with the serous surface of the pericardium by scratching and by pressure. The following observations were noted in these experiments: 1. Paracentesis of the pericardium at the level of the fifth and sixth interspace near the mammary line elicited pain in the neck, sharp and restricted to a point over the trapezius ridge. Penetration of the pericardium at high levels failed to produce pain. This pain was similar to that previously described from irritation of the central portion of the diaphragmatic pleura. So we are entitled to assume that the phrenic nerve endings are reflected over the lower portion of the fibrous pericardium. 2. Scratching or pressure of the wire on the heart itself produced no pain, although a peculiar feeling of distress and apprehension was induced by "tripping" the apex with the wire. 3. The inner surface or serous layer of the pericardium gave no pain response to irritation.—Capps, Joseph A.: *Pain from the Pleura and Pericardium*, Research Publications, Association for Research in Nervous and Mental Disease, Baltimore, Williams & Wilkins Company, 1943.

DERMATITIS CAUSED BY VARIOUS REPRESENTATIVES OF THE ANACARDIACEAE

IN TROPICAL COUNTRIES

E. D. MERRILL, Sc.D., LL.D.

Administrator of Botanical Collections, Harvard University;
Director of the Arnold Arboretum

JAMAICA PLAIN, MASS.

Two short papers that appeared in *THE JOURNAL* Sept. 4, 1943 inspired me to prepare this paper. One of these was entitled "Dhobie Mark Dermatitis" and the other "Dermatitis from *Semecarpus Anacardium*."¹ In the first paper, 52 cases were reported in which dermatitis resulted among American soldiers serving in India; articles of clothing worn by them had been marked with the juice of the marking nut, *Semecarpus anacardium*. In the second paper there was a report of 16 persons who were affected out of 50 who were exposed in sorting mail in Washington, D. C., that had been contaminated by a partly opened bottle of bhilawanol oil (marking nut oil) that happened to be included in the same sack of mail. In practice in India the oil of the marking nut, mixed with lime water or alum, is used by the native laundrymen as a marking ink for articles of clothing; it is insoluble in water and hence distinctly permanent. The somewhat caustic juice from the fruit walls of the common and widely known cashew nut (*Anacardium occidentale*) is similarly used. In the case of the latter species, when cooking the nuts by boiling or by roasting, one is warned not to stand where the steam or the smoke will come in contact with one's person. It is a well known fact that persons susceptible to *Rhus* dermatitis are frequently poisoned by merely standing in the smoke of bonfires in which parts of poison oak or poison ivy plants are being burned, and this applies also to the steam or smoke when cashew nuts are boiled or roasted.

My object in this paper is to record the fact for the benefit of medical men assigned to positions in the Old World tropics that in most parts of the region certain plant species do occur that, on contact, cause a distinct and often severe dermatitis corresponding exactly to *Rhus* dermatitis in the United States. All these deleterious species belong in the same natural family as do our poisonous species of *Rhus* (poison oak, poison ivy, poison sumac), the Anacardiaceae, and the active principle is the same in all cases. It is evident that as the war progresses there will be cases of dermatitis observed in the active and potentially active areas. It is scarcely necessary to prepare a botanical treatment of this subject, for one simply cannot educate all members of the armed services called on to operate in the forests and jungles to recognize at sight the relatively few poisonous plant species that may be encountered. After all, in practice it will be found that cases of dermatitis will occur chiefly among those men who fell certain types of trees and who inadvertently smear themselves more or less with an

M.: Dhobie Mark Dermatitis, *Bull. U. S. Army M. Dept.*, 1943, number 69, pp. 55-58. Goldsmith, N. R.: Dermatitis from *Semecarpus Anacardium* (Bhilawanol or Marking Nut) Spread by Contaminated Mail, *J. A. M. A.* **123**: 27 (Sept. 4) 1943. Waud, S. P., and Fein, H.: Dermatitis Venenata Caused by the Ink from the Bichi Nut, *Bull. U. S. Army M. Dept.*, 1943, number 69, pp. 59-60.

innocent looking sap of these trees. The point that needs repetition is that the average physician working with our troops may expect, on occasion, to encounter mild to rather severe cases of dermatitis caused by the victims coming in contact with certain trees or shrubs, and in such cases the indicated treatment is exactly the same as that used for ordinary *Rhus* dermatitis at home.

The Anacardiaceae are a family of woody plants of worldwide distribution, chiefly trees, but including some shrubs and vines. It is rather a striking fact that frequently species of this family that are contact poisons produce fruits that at maturity may be eaten with entire safety. Actually in the Old World tropics certain definitely poisonous species of *Mangifera* (mango) are widely cultivated for their edible fruits. The genera involved are *Rhus*, including its segregate *Toxicodendron*, with perhaps 200 species, fortunately few of them actually poisonous (those in the *Toxicodendron* group only), and confined to certain parts of North America, Japan and China, *Anacardium* with fifteen species, tropical America, one (*Anacardium occidentale*), the common cashew nut, introduced and abundant in the Old World tropics, *Gluta*, fifteen species, *Swintonia*, sixteen species, *Melanorrhoea*, eighteen species, *Melanochyla*, thirteen species, *Semecarpus*, ninety species, *Camposperma*, twelve species, and *Mangifera*, sixty species, all these genera characteristic of the Indo-Malaysian region; and *Metopium*, two species, *Comocladia*, thirty-five species, *Lithraea*, six species and *Pseudosmodium*, four species, all characteristic of tropical America. They are found chiefly in forested areas, but some grow in thickets and in fence rows. Many of them are fortunately by no means common, and, generally speaking, it is only a few species of any particular genus, such as *Mangifera*, *Semecarpus* and *Rhus*, that are actually poisonous.

There is, of course, a great variation in susceptibility in different persons, some being highly allergic, others being relatively immune to the poisonous principle. Curiously, the mature fruits of even the poisonous species of *Mangifera*, *Semecarpus* and *Anacardium* may be eaten with impunity, while the seeds of *Gluta* may be eaten with entire safety after cooking. In this family are a considerable number of genera which contain species widely cultivated for their edible fruits in various tropical countries, including representatives of *Spondias*, *Dracontomelon*, *Pleiogynium*, *Odina*, *Pistacia*, *Cyrtocarpa*, *Lansea* and *Harphyllum*. None of these are contact poisons.

These contact poison plants belonging in often very dissimilar genera are so well known to the natives familiar with the forest that in British Malaya, for example, the various species of such strikingly dissimilar genera as *Gluta*, *Melanochyla*, *Melanorrhoea*, *Semecarpus* and *Swintonia* are collectively known as *rengas*, cognate forms of this word in Java being *ingas* and in the Philippines (for *Semecarpus* species) *ligas*.

In general the various representatives of the Anacardiaceae have a more or less resinous sap which is sometimes slightly milky and which on exposure to the air soon becomes brown or black. The sap of some species of *Rhus*, *Gluta* and *Melanorrhoea* is the basis of certain types of lacquer widely utilized in the Old World. It is reported that workers in the lacquer industry develop a very high degree of immunity to what may be designated as anacardiaceous dermatitis. It is this sap that carries the poisonous properties of the various

species, and it occurs, of course, in greater or less abundance in all parts of the plant. This sap is never irritating on contact, the characteristic dermatitis not developing for some time after a person has come in contact with the plant or its juice. Yet such is the variation in immunity that highly allergic persons coming in contact even with old lacquered furniture may on occasion develop the dermatitis characteristic of *Rhus* poisoning. In the case of the common mango, while most persons can safely eat this magnificent fruit in quantity, occasionally persons will be found who will at once develop a characteristic mango rash on eating even a small amount of the fruit.

Instances have been reported of persons developing a characteristic dermatitis after having stood under some of these tree species during showers, and others by their merely coming in contact with the fresh leaves. Generally, however, dermatitis occurs only when one comes in contact with the plant sap, either fresh or old. Some of the species actually yield important commercial timbers, but difficulties are often encountered by persons handling the lumber, often long after the trees may have been felled. This for the reason that the sap may retain its highly irritant qualities for a long time, quite as in the case of the marking nut, when dermatitis occurred even after clothing marked with its oil had been laundered. In 1 case reported to me in Manila from Boston many years ago a carpenter working with imported lumber developed a very severe dermatitis and an examination of the wood showed that it was the Malayan *rengas* (*Gluta*), logs of which are sometimes exported, for it is a good cabinet timber.

The famous tropical fruit the mango (*Mangifera indica*) is normally innocuous, but this cannot be said regarding certain wild species of *Mangifera* characteristic of the Indo-Malaysian region, some of which are also cultivated about houses and in orchards for their edible fruit. With representatives of this genus it is the sap that should be avoided, one author intimately familiar with the vegetation of the Malay Peninsula stating "Our advice is always to treat respectfully Mango-like trees which smell of turpentine." The *binjai* or *uani* (*Mangifera caesia*), the *lanjut* (*Mangifera lagenifera*), the *bachang* (*Mangifera foetida*) and *kwin* (*Mangifera odorata*) are all contact poisons, yet in the Malayan region all are cultivated for their edible fruits. Of these the *lanjut* and the *binjai* are the most poisonous; even the vapor from freshly bruised tissues, the smoke from a bonfire of their leaves and branchlets, or raindrops falling through the crown of the tree may affect the skin. All the *Mangifera* species are large trees, and most of the species, other than the few cultivated ones, occur only in forested regions as widely scattered individuals. They are mostly Malayan, some extending northward to Burma, Siam and Indo-China.

The generally accepted idea is that the poisonous principle characteristic of certain genera and species of the Anacardiaceae is a very permanent nonvolatile oil, which on contact with the skin causes the characteristic dermatitis familiar to all physicians who have had occasion to treat cases of *Rhus* poisoning. It may safely be assumed that the poisonous principle, whatever it is, is the same for all representatives of the various genera listed, and in cases of dermatitis simulating that caused by our common poison ivy and poison oak or poison sumac, the indicated treatment is exactly that which the physician would use in any part of the United States for *Rhus* dermatitis. One can

scarcely escape the conclusion, from what has already been reported, that American troops serving in almost any part of the Indo-Malaysian region may come in contact with some of these poisonous species, and the probability is that physicians serving with the troops will have, on occasion, to treat cases of more or less severe dermatitis which will remind him of Rhus dermatitis with which he is familiar at home.

While there are plants in the tropics in other families than the Anacardiaceae that may cause dermatitis, I know of none in which the active principle is the same as that characteristic of the Anacardiaceae. Certain species of the Euphorbiaceae, with milky sap, may and do cause severe dermatitis, but this is caused by contact with the milky juice with which the growing parts of these plants are charged, an excellent example being the tropical American manchineel (*Hippomane mancinella*). In other representatives of this family difficulties may be encountered only when the milky sap comes in contact with mucous membranes, such as those about the eye; some of these euphorbiaceous plants are even reputed to cause such severe conjunctivitis that blindness may follow.

Aside from these contact poisons there is little to fear in the tropical jungles. Certain species of *Jatropha* in tropical America and representatives of a few other genera have intensely irritating stinging hairs, and this is also true of the numerous Old World species of the tree nettle (*Laportea*), shrubs and small trees, first cousins to the common nettle but much more vicious.

Contact with these shrubs or small trees causes an immediate sensation similar to that which one feels on touching red hot iron, and this intense pain is almost immediately followed by extensive water blisters, which continue to form for some time following exposure. The irritating principle in the case of the tree nettles is apparently formic acid, and the indicated treatment is to bathe the affected parts thoroughly with an alkaline solution.

Purely mechanical are the stinging hairs found on the pods and certain floral parts of the cowhage (*Mucuna*), and representatives of this genus occur in both hemispheres. Apparently in the case of the cowhage the resulting pain is due wholly to the mechanical effect of the very stiff, needle shaped stinging hairs. In India, and perhaps in other parts of the world as well, these stinging cowhage hairs, mixed with molasses as a carrier, are used as a remedy for tapeworm, the mixture being swallowed, the soft tissues of the tapeworm attracting the stinging hairs with apparently fatal affect to the tapeworm.

As with Rhus, contact with the poisonous plants briefly discussed will yield varying results. Highly allergic persons may be very severely affected, while immune or partly immune ones are affected slightly or not at all. On the basis of my own wide personal experience in the forests and jungles of the Old World, covering a period of twenty-two years, I was never affected by any of these reputedly poisonous species, although many times I have handled fresh branches over and over again in the course of preparing botanical material; and in the same period none of my numerous associates ever reported cases of contact poisoning. I speak as a field botanist rather than as a physician. On the whole I suspect that it will be only on rare occasions that cases of anacardiaceous dermatitis will be noticed. If such cases do show up, then apply the same treatment that one would use for Rhus dermatitis at home.

THE CORNELL SELECTEE INDEX

A METHOD FOR QUICK TESTING OF SELECTEES
FOR THE ARMED FORCES

ARTHUR WEIDER, M.A.

BELA MITTELMANN, M.D.

DAVID WECHSLER, Ph.D.

AND

HAROLD G. WOLFF, M.D.

WITH THE TECHNICAL ASSISTANCE OF MARGARET MEIXNER
NEW YORK

BACKGROUND AND LITERATURE

That each person with a neuropsychiatric disorder revealed subsequent to induction costs the government \$30,000 to \$35,000, that twenty-seven hospitals with a capacity for 33,000 patients are devoted to the care of veterans from the first world war with neuropsychiatric disorders, that approximately a billion dollars has been spent on the care of these patients and that 60 per cent of all ex-members of military services requiring hospitalization are admitted for neuropsychiatric disabilities are facts which have been repeatedly presented in the literature.

As the result of the work of neuropsychiatric examination boards in the United States, the American Expeditionary Force of World War I had a far smaller percentage of nervous and mental casualties than did the armies of our allies. Even so, 110,137 neuropsychiatric casualties occurred in the Army from April 1, 1917 to Dec. 31, 1919 at a rate of 26 per thousand. It has been estimated, furthermore, that had it not been for the psychiatric selection process 40,000 more casualties of this type would have occurred in our forces. No small wonder that the editors of the volume on neuropsychiatry of the History of the Medical Department of the United States Army of World War I should express the belief that it would have been advisable to reject totally all mentally unfit individuals at the draft boards rather than to have selected some of them for full or even limited military service.

Since the same problems still exist, methods that attempt to refine the selective process are being studied or devised. In his comprehensive treatise, Miller and his collaborators¹ point out that "men who are liable to breakdown can frequently be detected during enlistment. . . . Since the treatment of psychological disorders, as compared with others, tends to be disproportionately costly and difficult, prophylaxis is correspondingly important."

Rosenberg and Lambert,² in a review of 200 consecutive case histories of soldiers discharged from the Army at Camp Lee, Virginia, because of neuropsychiatric disabilities, found that 83 per cent had had symptoms before induction. It was concluded that "the majority of the psychiatric casualties we encountered could have been eliminated at the induction board if relatively simple social service data had been available." Bowman³ sug-

2. Rosenberg, S. J., and Lambert, R. H.: Analysis of Certain Factors in Histories of 200 Soldiers Discharged from the Army for Neuropsychiatric Disabilities, *Am. J. Psychiat.* 99:164, 1942.
3. Bowman, K. M.: Psychiatric Examination of Applicants in Armed Forces, *War Med.* 1:213 (March) 1941.

gested the use of the files of hospitals and courts, social service and school records by local draft boards in order to weed out unsuitable persons and to facilitate the work of the examining neuropsychiatrist. Other suggestions have been offered by Menninger and Greenwood,⁴ who felt that the work of the induction board psychiatrist was highly unsatisfactory since a reliable diagnosis could not be arrived at in three or four minutes. This was even more difficult because of the fact that the pertinent historical information was lacking.

Even with the assistance of supplemental technics, von Storch and his associates⁵ felt that it was impossible for one neuropsychiatrist to examine more than 50 recruits in one day and do an adequate job of it. It was their experience that no one neuropsychiatrist can do justice to more than 10 men per hour. The practice of allotting 50 selectees to one psychiatrist has been adopted at the Boston induction station, as was suggested by Bloomberg and Hyde.⁶

One type of selection is best exemplified by the method used at the Naval Training Station at Newport, R. I. Here the candidate is examined while he is naked, after he has been standing from three quarters to one hour for his physical examination. From a naval neuropsychiatric point of view this is an ideal time to examine the recruit, since he is physically and emotionally fatigued. Wittson and his associates,⁷ who have been using this method, find that of all men suspected at this initial examination one third are ultimately discharged.

It has been noted that in various Armed Forces Induction stations in the East (e. g. New York, Boston and Atlanta, and Fort Benning for Negro recruits) questionnaires of a neuropsychiatric nature are used. A statistically standardized procedure of broad and searching quality would be of inestimable value in preventing the induction of those who might not only destroy the morale of the fighting forces but may also do irreparable damage to themselves. This examination must pick out the obviously mentally disturbed and also those whose disability is subtly hidden or potential.

Porter⁸ suggests a list of fifteen basic personal attributes for inquiry which should enable one to prognosticate a breakdown under stress.

Flicker⁹ shows appreciation of the varied phases of the problem when he suggests that (1) something should be done in the matter of obtaining a psychiatric history, (2) 50 men to every neuropsychiatrist should be the case load for one day and (3) "a definite minimum neuropsychiatric blank be supplied, along the lines suggested by Aita, and that it be mandatory that this be completely filled out."

It becomes apparent from the consideration of the foregoing that it would be desirable to have a method which would attain uniformity, simplicity and objectivity, not to replace the intuition and experience of the neuropsychiatrist, but to supplement and improve his effectiveness. With this aim the Selectee Index was formulated.

AIM

The vast majority of persons who show evidence of difficulty in adjustment or "break down" under the circumstances of civil life can be expected to "break" under the circumstances of military life. Hence a procedure which would "screen" out the borderline and proved inadequate before induction would lessen the incidence of illness in the armed forces. To detect such persons is desirable because neuropsychiatric and psychosomatic disorders have become important military problems. Furthermore, because of a paucity of neuropsychiatrists, devices that are time and energy saving are essential.

The purpose of the Selectee Index is to furnish a quick and reliable means of detecting individuals who are likely to develop psychoneuroses and psychosomatic disturbances, especially peptic ulcer and allied syndromes. Although designed primarily for evaluation of selectees at induction stations, it may be employed in preinduction examination at Selective Service local boards as well as in replacement centers and in military hospitals.

METHOD

Numerous experiments involving test procedures, both standard and of our own devising, were carried out on a variety of groups of subjects (patients with peptic ulcer, anxiety states, other psychoneurotic states, psychotics, ambulatory hospital patients recovering from upper respiratory infections, medical students and selectees). As the result of these experiments an index was devised based on the results of three tests indicating the subject's neurotic and other abnormal reaction patterns as well as his self confidence, range of interests, decisiveness and the presence of sexual abnormalities.

These tests are self administered and may be given to individuals or to groups of persons. The tests require fifteen minutes to complete and may be scored in two minutes by any one with high school education. The method of scoring may be learned in less than one hour. The equipment for scoring the tests consists of three stencils, a table of equivalent weighted scores and a one page manual of instructions.

The first test presents an opportunity for occupational choice, designed to reveal the subject's range of interest, his work preferences and his acceptance of the male pattern. He is asked to indicate in a list of occupations those which he likes or dislikes. A previous study of homosexuals incarcerated at Rikers Island for asocial behavior, as well as other effeminate and homosexual subjects, demonstrated in a statistically reliable manner that certain occupations, e. g. interior decorator, dancer, window dresser, were chosen by these homosexuals with great frequency. This fact is utilized for the purpose of drawing conclusions concerning the individual's ability to accept the male pattern of our society.

The second test presents evidence of the subject's self evaluation. The subject indicates whether he believes that he would be "good," "poor" or is "in doubt" of his ability to manage specific situations. This test indicates the amount of self confidence, self esteem and decisiveness.

The third test, a questionnaire, consists of a neuropsychiatric and psychosomatic inventory of symptoms which are evidences of maladjustment. The questions in the inventory are of two types. Every fifth question and the last six, so placed for quick discernibility, are of a crucial nature, e. g. "15. Did you ever have a fit or convulsion?" These are called "stop questions" because

any selectee who exhibits such a major symptom must be stopped for more intensive appraisal. The others have less serious implications, such as "11. Are you easily discouraged?" In scoring the index it is this third test which contributes most to the total score and to the "screening" process.

It is worthy of emphasis that each item in the index was incorporated only after having been exposed to item analysis and statistical validation.

For comparison and evaluation, the tests were given to a group of selectees in an experiment arranged by the New York City Selective Service authorities. Each subject was interviewed for fifteen minutes by a leading civilian neuropsychiatrist who had a good appreciation of the requirements for army life. Moreover, these neuropsychiatrists had been given an outline describing an interview procedure designed to aid in detecting important symptoms and to give a degree of uniformity to the interviews.

Similar experiments were carried out at New York and Boston induction stations where the index was

used in conjunction with the routine neuropsychiatric interview.

The tests were also given to Army and Navy personnel about to be discharged for neuropsychiatric disorders. Here, test results were compared with actual military performance and the information acquired through intensive study at military hospitals.

RESULTS

A comparison of these groups with a normal population in regard to incidence of "stop questions" is shown in table 1.¹⁰ For example, less than 1 per cent of the normal and accepted groups suffer from alcoholism, while 5 to 10 per cent of the rejected and discharged groups do. Table 2 shows the frequency of "stop questions" for these groups. For example, 20 to 25 per cent of the normal and accepted groups have one or more "stop questions," while 70 to 83 per cent of the rejected and discharged men admit these significant symptoms. Table 3 shows the distribution of "weighted scores" ¹¹ for these groups. It should be noted that the

mean and standard deviation of the rejected group is considerably lower than that for the general selectee population and that the critical ratios between the groups compared are in all cases statistically significant. The effect of age on "weighted score" was studied, and it

was found that the mean for a specific age varied but slightly from the mean of the group.

The selectee tests have been given to 5,435 persons. Results are presented for 3,955 individuals. Those for the remainder are not presented because the results of the neuropsychiatric interview were not available. Performance results may later become available for this group.

In the following experiments each subject was examined with the index and by a neuropsychiatrist whose opinion was accepted as a basis for comparison.

* Weighted scores of 44 or less are the basis for referral for neuropsychiatric appraisal.

SERIES I

Results are given for 307 selectees from the Greater New York area. Eighty-six per cent of those men rejected by the neuropsychiatrist were also "screened" by the index.

10. In these tables the general selectee population is composed of the group of 887 accepts and 113 rejects.

11. The simple sums arrived at as the first step in scoring are called "raw scores." By means of a statistical analysis these scores are reduced to a scale of evaluation called the "Table of Equivalent Weighted Scores," which gives the "weighted score."

SERIES II

A group of 1,863 selectees from Boston and its environs was examined with the Selectee Index at the Boston induction station. Here 80 per cent of those rejected after neuropsychiatric interview were "screened" by the index.

SERIES III

A group numbering 1,390 was tested at the New York City induction station. Of the 179 men rejected for psychiatric reasons, 158, or 87 per cent, were "screened" by the index.

SERIES IV

Of 210 men discharged from the Army for neuropsychiatric reasons and 72 discharged from the Navy for similar disorders, the index "screened" 90 per cent and 88 per cent respectively.

SERIES V

In a series different from those described, 63 subjects who had already been rejected by neuropsychiatrists attached to Selective Service local boards were reexamined by means of a second neuropsychiatric interview

forces induction station for Georgia. The index "screened" all of the 27 persons rejected by the interview method. An experiment was arranged at the Fort Benning induction station for Negroes, and the tests were given to 150 subjects. Of the 4 men rejected for neuropsychiatric reasons, the index "screened" 3.

In these experiments a larger number of men failed the index than were ultimately rejected. There is some evidence to indicate that some of the persons who failed the index but were accepted will ultimately prove themselves to be inadequate. The confirmation of this postulation will have to be postponed until data on their performance in the Army are available. Other persons failed the index but were accepted because (a) a question had been misunderstood or misevaluated by the subject or (b) of defects in the construction of the Selectee Index. About one third of those who failed the index were finally rejected.

Conversely, 10 to 20 per cent of those rejected by the interview method are not "screened" by the index and for substantially the same reasons that have been mentioned. This discrepancy represents 1 to 4 per cent of the general population, as shown in the chart.

* Classifications as quoted by the various induction stations and military hospitals. † Number of subjects rejected by interview method.

‡ Number "screened" by selectee index.

Unfortunately hypertension was included by some neuropsychiatrists as a neuropsychiatric disability. The justification for such a classification of these patients is lacking.

and with the index. Here the index "screened" only those men who had been rejected as the result of the second interview. Thus, 43, or 87 per cent, of the 49 men rejected as the result of the second interview failed to achieve a passing score on the index. In other words, all persons rejected as a result of a failing index score were also rejected as a result of the second neuropsychiatric interview.

SERIES VI

As a further step in this checking process, 50 selectees were given the tests after having been interviewed. In those cases in which the test results disagreed with the findings of the interviewer, the subject was examined again by a second neuropsychiatrist. The second examination differed from the first in that the interviewer had before him the information uncovered by the index to guide him in formulating a final opinion. In 4 cases the added information caused the second interviewer to arrive at an opinion opposite to that of the first.

SERIES VII

To ascertain whether cultural differences in another part of the United States would modify the value of the index, Southern white and Negro selectees were examined in Georgia. The tests were given to 230 Southern white persons at Fort McPherson, the armed

The equivalent of a seventh grade elementary education is necessary for the adequate understanding of the test items. In the northeastern part of the United States between 5 and 10 per cent of the population has not achieved this educational level and therefore the index is not applicable to this group. In certain parts of the South as high as 70 per cent of the Negro population could not take the index.

RECOMMENDATIONS FOR THE USE OF THE
SELECTEE INDEX

Since the index is self administered it might readily be included in the "processing" now in use for the "screening" of selectees. There would be a great advantage in having the index administered at the same stage at which the men are given a preliminary Wassermann test by the Selective Service authorities. It would then become a part of the history sent to the induction station along with the selectee on the day on which he is to be examined. This would present the examining neuropsychiatrist with a picture of the subject's neuropsychiatric state and would enable the physician to arrive at a more accurate and effective decision than at present. The ease with which the index is administered and scored makes it possible to use women, either civilian volunteers or military personnel, in this work.

Should this procedure prove impractical the Selectee Index could be used at the induction station, the same result being achieved as long as the index is administered and scored prior to the subject's neuropsychiatric interview. Use of the index at this stage, however, would be more costly in time and personnel.

Percentage of neuropsychiatrically unfit (as ascertained by interview method and military performance) "screened" by the Selectee Index.

It is recommended that a man achieving a passing score on the index be seen for a minute or two for confirmation. On the other hand, if he received a failing score the material uncovered by the index can be promptly used for establishing the selectee's status. Thus the neuropsychiatrist would have more time to spend with the frank and borderline individuals, which may comprise up to 40 per cent of all candidates. Under these circumstances this group referred for special consideration would contain most of those who should be rejected. For one reason or another the neuropsychiatrist may decide to accept a certain proportion of those who have received failing scores. This must be done on the basis of the examiner's interpretation of the selectee's neuropsychiatric equipment. From 80 to 90 per cent of those judged militarily unfit by the neuropsychiatrist are "screened" by the index.¹²

The index may also be used as an aid in classifying grossly, patients who have already reached the neuropsychiatric wards of Army and Navy hospitals. The information gathered by the index is valuable as a supplement to the hospital history of such patients. Here it may be given routinely by the admitting nurse. In such use of the index it would be more important to examine the individual answers to questions than merely to record the final score.

SUMMARY—CRITICISM AND EVALUATION

The Selectee Index has shown itself to be effective in indicating the presence of anxiety states, hypochondriasis, asocial trends, convulsive disorders, migraine, asthma, peptic ulcer and allied syndromes. It focuses attention on borderline clinical states that may be missed because they fall between other departmental classifications (i. e. so-called psychosomatic disorders; table 4). It is less effective in the "screening" of those likely to exhibit so-called monosymptomatic disturbances, e. g. hysterical palsies, and the prepsy-

chotic and early psychotic states. It is also defective in detecting obsessive states. Furthermore, it requires literacy which makes its universal application impossible. Although responses may be falsified, in practice we have noted this infrequently.

An important asset in the use of the Selectee Index is the ease and simplicity of administering and scoring. It is an effective time saver in placing before the interviewing neuropsychiatrist a clinical profile of the subject's personality defects. By bringing to the attention of the examiner a body of data as well as an indicator of the qualifications of the selectee, it should improve his accuracy and judgment. It is the brevity of the tests, their simplicity of scoring and their focus on special neuropsychiatric problems that recommend the use of the Selectee Index.¹³

Clinical Notes, Suggestions and New Instruments

MULTIPLE METATARSAL FRACTURES ASSOCIATED WITH OSTEOGENIC SARCOMA

HENRY W. MEYERDING, M.D., ROCHESTER, MINN.

The following report of a case of multiple metatarsal fractures associated with periosteal osteogenic sarcoma is worthy of record:

REPORT OF CASE

A boy aged 15 years was seen at the Mayo Clinic Oct. 25, 1929 because of a growth in his nose. He stated that he had consulted a physician because of frequent attacks of epistaxis, from which he had suffered for many years. Seven months prior to admission the physician, thinking that he would remove a polyp, found a firm tumor and removed a section of tissue, which on microscopic examination was reported as showing a spindle cell sarcoma. The tissue was submitted to a distinguished pathologist, who made a diagnosis of "cellular fibroma or sarcoma," and two treatments of radium were given. We made a diagnosis of benign fibroma of the nasopharynx. The tumor was treated by diathermy and radium, after which the patient had complete relief of symptoms. There was no other complaint at this admission, and the roentgenograms of the head and of the thorax were negative. The blood count, the results of urinalysis and the Wassermann reaction of the blood were also negative.

In April 1930, six months later, the patient returned to the clinic, a distance of 1,200 miles. He stated that two weeks prior to this time tenderness and a few days later swelling

Fig. 1.—a, dorsal appearance of forepart of right foot, which shows spindle cell periosteal thickening in the distal half of the second metatarsal bone. There is pronounced elevation of the shaft of the second right metatarsal bone with no evidence of fracture. b, lateral view.

had developed across the forepart of the dorsum of the right foot. With rest and hot applications the swelling had reduced in size, but an apparent thickening was situated near the head

12. With a variation of the scoring method, 5 to 15 per cent of the general population is referred for special consideration. Although with this method only about 55 to 60 per cent of the total militarily unfit are earmarked, the large majority of this group will be found unfit on examination; a fraction will be borderline.

13. Test blanks and scoring materials are available to responsible agencies on request to the authors at Cornell Selectee Index Project P206, New York Hospital, 525 East Sixty-Eighth Street, New York. From the Section on Orthopedic Surgery, Mayo Clinic.

of the second metatarsal bone. The roentgenologist reported pronounced elevation of the periosteum of the shaft of the second right metatarsal bone with no evidence of fracture; roentgenograms of the thorax were negative. The forepart of the foot was tender on direct and lateral pressure. The patient did not recall an injury to the foot. Opinion varied as to the diagnosis: periostitis, infraction (Freiberg's infrac-

was feeling very well and had gained 10 pounds (4.5 Kg.) during a period of four months. Ten days prior to this admission, however, he had stepped on the right foot with the left foot and had injured the region of operation. Roentgenographic examination at home had been reported as showing sarcoma of the third metatarsal bone four days prior to admission. Our roentgenologist reported negative findings in the thorax, and a tumor involving the shaft of the third metatarsal bone, but no recurrence in the region of the second metatarsal stump. There was an enlargement of the lymph nodes of the groin. Excision of a node from the groin was advised and I felt that the tumor of the third metatarsal bone should be malignant in view of the previous pathologic findings but that possibly it was a fracture with callus (metatarsal fracture). Dec. 23, 1930 a lymph node was removed from the right groin, and on pathologic examination it was reported to be the seat of inflammation. The third metatarsal bone was exposed through a dorsal incision, and a grayish tumefaction with definite fracture was demonstrated. In view of the home physician's opinion, the previous pathologic diagnosis of osteosarcoma, the roentgenologist's report of tumor and the anxiety of the patient's mother, it was thought best to excise the metatarsal bone and make further studies to distinguish sarcoma from fracture with callus. This procedure was carried out, and subsequently the pathologist reported periostitis and an old fracture with formation of callus. Further irradiation was not advised, and the patient made an uneventful convalescence, after which he returned home on the seventeenth postoperative day. About three months later the mother reported that he was well, gained weight, slept well and walked well (fig. 3 *a* and *b*).

Six months later roentgenograms were negative except for periostitis. Approximately nine months later roentgenograms were forwarded to us which revealed periostitis of the first and fourth metatarsal bones with apparent fractures. About a month later the patient returned to the clinic for further treatment because of pain in the foot following a period of walking for four days. Roentgenograms were taken and revealed periostitis with fracture of the first and fourth metatarsal bones of the right foot (fig. 4 *a* and *b*) but those of the thorax were negative. The patient also had a severe infection of trichophytosis and received treatment under the supervision of a dermatologist. There were enlargement and tenderness of the inguinal lymph nodes. The temperature was normal. The patient improved rapidly under treatment and was able to walk well. He returned to his home Oct. 27, 1931. He was advised to send roentgenograms to us at a

Fig. 2.—Tissue from second metatarsal bone. *a*, $\times 185$; *b*, $\times 500$

tion) and periosteal sarcoma (possible metastasis) being considered in the absence of definite roentgenologic evidence of fracture. Roentgenograms of the opposite foot and of the long bones of the other parts of the body proved to be negative. The patient's mother demanded that an exploration be made, as she had been told by the home physician that the mass in the metatarsal region was a sarcoma.

Operation was performed on April 9, 1930, at which time a hard, spindle shaped bony mass, involving the distal half of the shaft of the second metatarsal bone, was resected. The pathologist's preliminary opinion was that the lesion was an exostosis but later after decalcification, his final report was osteosarcoma, grade 2 (Broders' method). Two low voltage roentgen treatments were given to the foot. The wound healed by primary intention and one month after the operation the patient returned to his home, where he remained under the supervision of his physician (figs. 1 *a* and *b* and 2 *a* and *b*).

Roentgenograms taken five weeks after operation showed resection of the distal two thirds of the second metatarsal bone, and the remainder of the metatarsal bones were normal. Roentgenograms of the thorax were negative. Three months later the patient had gained in weight. His weight at this time was 137 pounds (62 Kg.), whereas eighteen months previously it had been 100 pounds (45 Kg.). He had received thirty-five injections of Coley's toxins, $\frac{1}{4}$ to 13 drops, during a period from June to August. Roentgenograms did not show any recurrence in the remaining proximal third of the second metatarsal bone, but there was some atrophy of the bones of the foot. Roentgenograms of the thorax were negative. Another low voltage roentgen treatment was given to the foot (Aug. 18, 1930). The patient was walking and seemed in good health. The examination of the nose did not show any recurrence of a lesion. The patient returned home.

About four months subsequent to the foregoing visit, the patient again reported for observation. He stated that he

Fig. 3.—*a*, anteroposterior view, May 6, 1930, demonstrates partial resection of the second metatarsal bone. Note normal appearance of other metatarsal bones. *b*, anteroposterior view of right foot four months later, which shows resection of a portion of the second metatarsal bone and a fracture with pronounced periosteal thickening of the third metatarsal bone (march fracture).

later date so that they might be compared with those that we had of the foot. At this time there was no evidence of recurrence of the nasal tumor.

At the time of the foregoing visits I was suspicious of a metatarsal fracture and questioned the patient as to the pos-

sibility of an old injury of the right foot. For the first time he remembered that he had been injured four years prior to this admission. He stated that in October 1927 a horse fell on his right foot, which was crushed and held by a steel stirrup, following which there were pronounced ecchymosis and swelling like a watermelon. He further stated that he had been unable to walk on the foot for three weeks and that it had been two months before the foot felt well. Furthermore,

Fig. 4.—a, anteroposterior view which demonstrates partial resection of the second and third right metatarsal bones and evidence of fracture and periosteal thickening of the fourth right metatarsal bone. There apparently also is a fracture of the first right metatarsal bone with secondary cortical thickening. b, lateral view.

he said that two years before admission, while he was running, something gave way in the foot and he could hardly walk because of pain, and he thought that there had been a little swelling in the foot before it gave way. It was then that he had consulted a physician, who took a roentgenogram and made a diagnosis of sarcoma of the metatarsal bone.

July 29, 1932 the patient was admitted again at the clinic; this time he was feeling well and his weight was 158 pounds (72 Kg.). He walked at least 4 miles a day without difficulty except for a hammer toe. There was no evidence of recurrence of the nasal tumor, and the roentgenograms of the lungs were negative. The roentgenograms of the right foot, however, showed the region of resection of the second and third metatarsal bones and the fractures of the first and fourth metatarsal bones which had healed. Aug. 1, 1932 operation was performed while the patient was under local anesthesia. Because of the deformity a portion of the proximal phalanx of the fourth toe was excised. There was no recurrence of the tumor. The pathologist's examination of the bone gave negative results. The trichophytosis was improved.

Fig. 5.—a anteroposterior view taken May 10, 1934, which demonstrates resection of the second and third right metatarsal bones, and the fractures of the first and fourth right metatarsal bones healed and the callus absorbing. b, lateral view.

The patient returned home in one week and wished to know if he could play basketball.

May 9, 1934 the patient brought his sister to the clinic and reported for a reexamination himself. His weight was 168 pounds (76 Kg.). He had not had any pain or recurrence of symptoms in the foot and had been able to walk 20 miles with no sign of trouble. There had been no loss of weight. The roentgenograms of the thorax were negative. The ones

of the foot showed some thickening of the periosteum of the fourth metatarsal bone and absence of the second and third metatarsal bones (fig. 5 a and b). Examination of the nose did not show any recurrence of the tumor. The blood count had been normal and the results of urinalysis negative throughout the entire time this patient had been under our observation.

The patient reported by letter in February 1938 stating that he had not had any further trouble with his leg or foot and had not had any further treatment. His weight was 190 pounds (86 Kg.) and he was in perfect health. He had been working daily in a shingle mill, where he had had to carry heavy blocks of wood all during the working hours.

April 10, 1943 the patient was seen again at the clinic because of another nasal hemorrhage. He stated that about two months prior to this admission his physician had removed a nodule from his nose. Examination did not reveal any evidence of recurrence of the nasal tumor, but there was suppurative hidradenitis of the left axilla, for which the patient was given three low voltage roentgen treatments. The blood count and the results of urinalysis were negative. He stated that he had had no difficulty whatever with the right foot and had been able to work a full day and to walk miles.

COMMENT

This case has been most interesting and I have followed it for many years. During this time I have made a study of metatarsal fracture and have written about it.¹ The second metatarsal bone, which was resected at the time of the first operation, had been saved. The pathologist, Dr. Broders, was requested to reexamine this tissue and on Sept. 10, 1943, thirteen years postoperatively, sent a report to me. He stated that in his opinion the lesion of the second metatarsal bone represented a "periosteal osteogenic sarcoma" and selected two photomicrographs (fig. 2 a and b). I believe that this is a case of multiple metatarsal (march) fractures of the right foot in which the tissue of the primary lesion of the second metatarsal bone had undergone malignant change.

While I have had sufficient opportunity to recognize the wide divergence of opinion concerning the interpretation of microscopic findings in cases of lesions of bone, I feel that this patient originally had a metatarsal fracture. The possibility of sarcoma of the nose with metastasis to the metatarsal bone was considered by his physician and surgical treatment insisted on by the parent, all of which led to excision of the tumor mass which Dr. Broders diagnosed as osteogenic sarcoma. I shall quote directly from my surgical notes made on April 9, 1930: "We were suspicious of a periosteal sarcomatous malignancy and thought best to take out the tumor. A specimen of the tumor was sent to the laboratory for decalcification and study. The tumor was hard and may be osteogenic in type. I tried to get a history of trauma, thinking the condition might be a low grade periostitis following injury, but we were unable to prove any injury at this time." This case, therefore, represents a thirteen year cure of osteogenic sarcoma with multiple metatarsal fractures.

Growth of Scientific Knowledge on the Vitamin Needs of Man.—The growth of our understanding of the vitamin needs of man is a record of much blundering ignorance, some wishful thinking and a slow progress through controlled observation and experiments on man and other beasts. Blundering ignorance as to food composition and man's dietary needs brought on us the classic vitamin deficiency diseases (rickets, scurvy, beriberi, pellagra). The striking results of good food therapy in these diseases have engendered in our generation the utopian hope that a greater abundance of vitamins will rid man of nearly all real and imaginary ills. But more and better controlled observations and experiments will restore sense and scientific sanity, will remind us again that life is just not that simple.—Carlson, A. J.: The Growth of Scientific Knowledge on the Vitamin Needs of Man, *Journal-Lancet*, November 1943.

Special Article

AMERICAN HEALTH RESORTS

TYPES OF TREATMENT ADMINISTERED AT HEALTH RESORTS

M. B. JARMAN, M.D.

HOT SPRINGS, VA.

These special articles on spa therapy and American health resorts were prepared under the direction of the Committee on American Health Resorts. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the committee. These articles may be published later as a Handbook on Health Resorts.

For convenience of discussion the types of treatment administered at health resorts fall under two headings: (1) the regimen which is common to all health resorts and which has to do with such items as rest, exercise, and dietary regulation; (2) therapeutic procedures which are used extensively in health resorts but which vary at the different resorts depending on their natural facilities.

THE REGIMEN

It is difficult to visualize a regimen at any health promoting institution in which emphasis is not placed on the regulation of rest, exercise and diet. These measures constitute the difference between the existence of a regimen and the lack of it. The regimens at different resorts differ in details but these items are basic. They supply the framework into which the particular natural resources of therapeutic value of a given resort may be fitted in the planning of the therapeutic program.

One resort may utilize to the fullest extent the components of climate, such as sunshine, temperature and relative humidity, with which it is endowed by virtue of its geographic location. Another makes use of sea bathing and the climate which goes with its situation on the seacoast. Others use mineral spring waters for drinking and bathing purposes. When these and other natural resources are used at health resorts for health purposes they are not used alone but as a part of a regimen planned with proper consideration for the needs of the patients treated.

THERAPEUTIC AGENTS EXTENSIVELY USED AT HEALTH RESORTS

Separate articles in this series have been written on "underwater gymnastics," "climate and disease" and "thalassotherapy." No further mention will be made of these. Other types of therapy extensively used but not the subjects of separate articles will be discussed briefly. For the most part these consist of various forms of physical therapy. Years before medical schools¹ began to teach the subject or before hospitals or clinics installed departments of physical therapy, many health resorts were making extensive use of some of its forms. Among these are hydrotherapy, which includes both the drinking of water and baths, light, massage, heat, mud and to a lesser degree electrotherapy.

Hydrotherapy.—A large percentage of health resorts are spas. The use of water in treatment is the distinguishing feature of such institutions. At some the drinking of water is stressed; at others, baths are emphasized; at many, both are used and these are combined with other health promoting procedures which constitute the regimen of the spa.

Drinking Water.—When the drinking of a particular water is stressed at a spa, such a water is often referred to as a "mineral water." A satisfactory definition of a "mineral water" is difficult to find. Here are some samples: The Quality of Water Division of the United States Geological Survey finds it convenient for statistical purposes to define a mineral water as "one sold in a bottle!"² The International Food Congress held in Paris in 1909 adopted the following definition: "A mineral water is a natural water proposed for consumption on account of its special therapeutic or hygienic properties." The geologist defines a mineral water as "one derived from deep-seated natural sources." The chemist thinks of a mineral water in terms of the amount of dissolved minerals it contains and hesitates to classify a water under this heading unless it contains at least 1 gram of dissolved minerals per liter of water. From the medical point of view mineral water has been defined as "one from natural sources which has therapeutic value." Other definitions are "any natural water which is used on account of special constituents" and "a natural water containing sufficient salts or gases in solution to give it its properties and peculiar taste." From these samples—and others not listed—one in search of a definition of "mineral water" has a great variety of proposed definitions from which to make a choice.

At some spas the drinking of water is almost dramatized. It is done according to precise directions as to time and amount and sometimes to the accompaniment of music. This provides one means for getting the patient to take enough water and seems to give some types of patients a sort of spiritual uplift. Water taken internally serves as a diuretic, and some waters are effective saline cathartics.

There are those³ who feel that some natural waters possess peculiar properties of therapeutic value—now resting on an empirical basis—which will be established scientifically at some future date when the methods of scientific investigation shall have been improved sufficiently and applied to the solution of the problems involved. In support of this feeling attention is directed to well known examples in the history of medicine in which therapy was long used and well established on an empirical basis, only to be explained scientifically some time later. In the field of mineral waters an example often cited is that of the springs in Austria famed as "goiter waters" years before the discovery of the iodine content of the water helped to explain its effect on the function of the thyroid gland. When claims are made for unusual therapeutic values of waters, suggested explanations for such claims often include reference to "catalytic agents" or "radioactivity." Physicians who admit freely that chemicals occurring in natural waters will bring about the same

3. Baudisch, Oskar, and Davidson, David: Natural Waters in the Light of Modern Research, Arch. Int. Med. 40: 496-520 (Oct.) 1927.

pharmacologic action as do chemicals derived from other sources when administered in the same dosages become skeptical when the claim is made that the chemicals in natural waters will bring about a pharmacologic action different from that of the same chemicals derived from other sources. The application of new theories and improved technic in research may in the future prove that chemicals which are now believed to be the same are in reality not exactly the same. Such a development might explain in scientific terms some of the results of mineral water therapy which now rest on an empirical basis.

Many physicians who prescribe the use of mineral waters and others who have given some thought to the subject are of the opinion that more often than not the most important chemical in the prescribed potion is water. The psychologic effect of prescribing mineral water according to exact directions is recognized fairly generally. Another article in this series deals with trace elements in waters. It is not likely that unusual claims made for mineral waters will be recognized by the medical profession unless such claims can be established when judged by scientific standards of the level applied in the evaluation of other therapeutic measures. In spite of this, physicians of spas have learned in many instances to make use of the waters at hand for drinking purposes in planning the regimen of the spa; and, in the effect that drinking of the mineral water has on the feeling of well being of the patient, it is by no means the least important part of such a regimen.

Baths.—The great variety of baths given at spas can only be listed here. Among the more important are the onge bath, tub bath, evaporation bath, whirlpool bath, carbonated bath (Nauheim), steam bath (Russian), mud pack or bath, sitz bath, medicated bath, brine bath, sulfur water bath, cabinet baths of several varieties, cold spray, needle douche or spray, alternating hot and cold douche (Scotch), fan douche, Vichy douche and Aix douche. Some spas are equipped with pools adapted for administering underwater gymnastics. Continuous baths are more likely to be used in institutions for the treatment of the mentally sick, and baths of the type given in the Hubbard tank are more common in the departments of physical therapy of hospitals.

For detailed descriptions of these baths, the technic of administering them, their physiologic effects and the indications for their use, the reader is referred to modern textbooks on physical therapy.⁴

In the administration of hydrotherapy at health resorts an attempt is made to take advantage of the natural resources with which the particular resort is endowed. One such resort may have an abundance of naturally carbonated water. Such an institution is supplied by nature with one of the essentials of the carbon dioxide (Nauheim) bath. Advantage is taken of this natural resource, and the resort is organized accordingly for treating patients suffering from chronic cardiovascular diseases. A warm spring in a suitable climate may determine the site of an institution for treating victims of poliomyelitis. Nature provides the warm water and the climate, and man develops a properly equipped and staffed institution in this location for the use of underwater gymnastics and other recognized

treatment for such patients. Another resort may have an abundance of naturally hot water. Advantage is taken of this circumstance, and the resort is equipped to give baths in which the physical properties of the water—aside from any consideration of its chemical content—are of prime consideration.

At the better spas hydrotherapy is administered under medical supervision. The prescribing physicians look on this as a means of utilizing the facilities at hand to the best advantage in giving the patient as a part of his regimen a well established and a very useful form of treatment.

Light.—Light is recognized as a useful therapeutic agent. The sun is an inexpensive source of light. Solar radiation does not reach all parts of the earth's surface with equal intensity. The intensity varies with the latitude, season, hour, elevation and atmospheric conditions, such as the moisture content and the presence or absence of dust and smoke. For these reasons health institutions have been located in certain parts of the world because of the relative intensity and constancy of the solar radiation. In other words, the site of the institution is determined by this particular natural resource just as the site of a spa is determined by another natural resource, namely a group of springs. The Swiss Alps are an example, and there are many localities in the United States adapted by nature for this purpose.

The two chief components of sunlight of recognized use in therapy are infra-red rays and ultraviolet rays. Because sunlight is not subject to control, because one type of radiation may be desired without the other and for the further reason that there is an abundance of enterprising manufacturers of electrical apparatus, both types of rays have been produced artificially. Textbooks⁵ on physical therapy describe this apparatus, tell how to use it and give the present concepts of the physiologic actions of the different types and the indications for their use.

Light supplied by direct rays from the sun and light supplied by artificial means provide a type of therapy extensively used at health resorts.

Massage.—This form of physical therapy, extensively used at health resorts, has been the means of giving a great deal of comfort to a great many people. Manual massage and mechanical massage have both been used. Excellent descriptions of the technic⁶ and the present concepts of the physiologic effects⁶ of massage can be found elsewhere. Manual massage given by trained masseurs under medical supervision constitutes an important part of the regimen at many resorts. Some health resorts are equipped with a complete set of machines of the type devised by Dr. Gustaf Zander of Stockholm for active and passive exercise of the voluntary muscles. Even at resorts or hospitals where these machines have been installed at great expense and are still available, little use is made of them because it has been found that the purpose for which they were designed can be accomplished more effectively, more safely and less expensively by other means. The physician, whether at a health resort or not, who has at

his command intelligent men and women well trained to give massage is armed with a therapeutic tool the value of which is difficult to estimate when measured in terms of the help and comfort rendered to patients.

Heat.—A recently published textbook⁷ on physical therapy devotes one hundred and thirty pages to the subject of thermotherapy and many more pages to diathermy. To such a textbook one should go for information as to the sources of heat both for local and for general application, its physiologic effects, and indications for and contraindications to its use. Heat is mentioned here simply because it is used extensively at health resorts as it is wherever sick people are treated. As a means of applying heat some resorts utilize their natural resources, such as hot water or mud, for the purpose but few confine themselves solely to these methods.

Mud.—Mud baths and mud packs are sometimes used as a method of applying heat. Muds have been classified according to their diminishing silicate content as (1) purely mineral, (2) mainly mineral and (3) mainly vegetable.⁸ The application of mud therapy consists of baths in specially built tubs or mud pools and the local application of mud packs. The use of mud in treatment is a much more common practice at European resorts than at those of America. As one example of this difference I found frequent references in European literature to the use of mud in the treatment of disorders of the genitourinary tract, whereas in a modern American textbook⁹ on gynecology and two recently published textbooks¹⁰ on urology I was unable to find a reference to the use of mud in these specialties. It appears from examination of the literature that American physicians, with some exceptions, are in accord with the sentiments expressed in these statements: "Often vague claims are advanced for specific therapeutic actions of certain types of mud. There is as yet no convincing proof that any such mud contains any constituents which enhance its effectiveness, when applied to the surface of the body. . . . It would seem that there are no particular advantages of mud packs over the simpler and cleaner methods of local application of heat."¹¹

If the application of heat to the surface of the body is needed, the use of mud provides one method by which it can be done. This method is made use of as a part of the regimen at European and—to a lesser extent—at American resorts.

Miscellaneous.—Many other types of treatment, of course, are administered at health resorts. The various types of electrotherapy are often made available to complete the physical therapy setup. One form of this—either conventional or short wave diathermy—is now used almost universally at resorts as a method for deep administration of heat. Since the people who go to health resorts are subject to the same ills as are people in general, no type of treatment is excluded.

Council on Pharmacy and Chemistry

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT.
AUSTIN E. SMITH, M.D., Secretary.

USE OF ESTROGENIC SUBSTANCES FOR UTERINE BLEEDING

Clinical study of irregular menstruation during the last decade has suggested to many observers that the occurrence of prolonged flows, excessively vigorous flows and unduly frequent flows may all be evidences of hypofunction of the ovaries. Quantitative information is not available to decide whether this means decreased amount of estrogenic hormone production or of progesterone production or chronologic variation in the cyclic production of these materials. The most frequent accompaniment of such bleeding history has been the persistence of the estrogenic effect in the endometrium, sometimes accompanied by the development of the picture known as glandular and cystic hyperplasia of endometrium. Carefully conducted clinical experiments have indicated that such flowing may be interrupted by the use of large doses of estrogenic hormone or synthetic estrogen. Some attempts have been made to restore regular cycles of bleeding by administration of estrogen followed by a combination of estrogen and progesterone, or estrogen followed by progesterone alone. The clinical benefits obtained by such methods have been at least promising, although there is not adequate evidence to justify claims for cure of a condition which is frequently persistent in terms of months or years.

Before such therapy is applied, it is considered important that careful investigation should be made to eliminate other causes of bleeding tendencies systemically and also to eliminate local pelvic disorders of neoplastic or inflammatory type. Occasionally it may be wise to use very brief courses of estrogen to arrest bleeding so that such studies can be carried out immediately after the cessation of the flow. With such precautions in mind, additional uses of estrogen seem warranted, and the following claims will be recognized in N. N. R.:

It has been found possible to interrupt the prolonged and excessive flowing of many women with uterine bleeding of probable endocrine origin by brief courses of intensive estrogenic therapy. This is considered safe practice only when the interval of freedom from bleeding is used to eliminate local pelvic lesions as the cause of the flowing. The subsequent administration of sequences of estrogenic substances and progesterone to reestablish cycles of flowing is a possible method of alleviating a condition which is widely believed to result from deficiency of one or both of the ovarian hormones.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Secretary.

DIETHYLSTILBESTROL (See New and Nonofficial Remedies, 1943, p. 403).

The following additional dosage form has been accepted:
GEORGE A. BREON & COMPANY, INC., KANSAS CITY, MO.
Tablet Diethylstilbestrol: 5.0 mg.

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1943, p. 590).

The following dosage form has been accepted:
McKesson & Robbins, Inc., Bridgeport, Conn.
Tablets Thiamine Hydrochloride: 0.5 mg., 1 mg. and 3 mg.

NICOTINAMIDE (See New and Nonofficial Remedies, 1943, p. 598).

The following dosage form has been accepted:
WILLIAM R. WARNER & CO., INC., NEW YORK
Ampul Solution Nicotinamide, 100 mg. per cc.: 1 cc.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 NORTH DEARBORN STREET - - CHICAGO 10, ILL.

Cable Address - - - "Medic, Chicago"

Subscription price - - - Eight dollars per annum in advance

Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, JANUARY 22, 1944

SUBSCRIPTION AND FELLOWSHIP DUES PAYABLE NOW

To simplify the payment of annual dues for subscription and fellowship, a colored slip combining the functions of statement and pre-paid return envelop is enclosed in this issue of *THE JOURNAL*. If you have not already remitted, please remember that subscription and fellowship dues are payable in advance. Your cooperation now will obviate the necessity of billing you personally. The number of subscribers to *THE JOURNAL* is at an all time high—strong evidence of its value to physicians whether in civilian or in military practice. To prevent any interruption in your subscription, return the colored slip with your remittance now (if not already paid). The A. M. A. special journals and *Hygeia*, with their respective subscription rates, are included on the slip. Payment for any of these journals may conveniently be included with your remittance for the annual dues.

PATHOLOGIC LESIONS LIKE THOSE OF RHEUMATISM

The possibility that the cardiac and other lesions in rheumatic fever might be the result of reactions of hypersensitivity to bacterial products has received much attention. Many attempts have been made to produce Aschoff bodies by injecting bacteria into sensitized animals, but so far without conclusive results. The rheumatic lesions are apparently of a strictly specific nature. In the course of their study of tissue reactions of rabbits hypersensitive to serum, Rich¹ and his associates observed not only arterial lesions apparently identical with those of periarteritis nodosa but also

cardiac lesions resembling closely the lesions of rheumatic carditis. The rabbits were killed one to five weeks after the systemic reaction to horse serum.

In nature and situation cardiac lesions in such rabbits corresponded closely to the lesions of rheumatic carditis: there was focal edema of the connective tissue with disintegration of collagen fibrils; also pericardial, valvular and mural inflammatory infiltrations with cellular foci in the endocardium and about the arteries in the myocardium. Besides macrophages and lymphocytes these foci contained cells peculiar to the Aschoff body, particularly about areas of degenerated collagen. These structures in the heart of rabbits hypersensitive to horse serum are well illustrated in the paper by Rich and Gregory.²

There is no question that the rabbit lesions described closely resemble those of rheumatic carditis. Rich and Gregory discuss in detail the "circumstances compatible with the view that the lesions of rheumatic fever may be the results of focal reactions of the anaphylactic type" but without making any claims that the genesis of rheumatic fever has been explained. Their results are significant, however, because they indicate promising lines for further study. Reactions of anaphylactic nature may play a larger part in human disease than now understood.

The article by Selye and his associates in this issue of *THE JOURNAL* (page 201) on the hormonal production of arthritis describes results of an elaborate experimental attack on rheumatic and related problems from a different angle. In brief, the Canadian investigators report that in animals, particularly the rat, relatively large doses of desoxycorticosterone acetate under certain conditions can cause polyarthritis associated with the formation of Aschoff bodies in the heart and at times periarteritis nodosa, besides nephrosclerosis and hypertension.³ This polyarthritis may microscopically resemble that of rheumatic fever. It was produced more readily in thyroidectomized or adrenalectomized than in intact rats, especially on exposure to cold. The results are interpreted to indicate that "the adrenal cortex may play an important role in the pathogenesis of rheumatic and rheumatoid conditions in man."

As the report does not mention bacteriologic studies of the experimental animals, the question of the possible role of infection in the results, especially in the acute polyarthritis, must be left open at this time. The results in general, including those of the survey of the clinical literature, do appear to support the view that "hormonal factors can act either as causative

or as predisposing agents in the production of joint lesions." These experiments on the actions of the adrenal cortex in the production of disease open another promising field for further investigation.

MAINTENANCE OF EDUCATIONAL STANDARDS IN MEDICAL EDUCATION IN WARTIME

The freedom of universities to choose their faculties without interference by political, family, social or other influences is a strong bulwark of education. This truth, highly important at all times, is no less valid now, particularly in medicine, dentistry and engineering. These forms of specialized training contribute immediately to the prosecution of the war. The maintenance of standards in teaching concerns the future of universities as centers of education and research. In medicine the care of patients, both civilian and military, is an additional responsibility of university staffs.

Our principal efforts are now bent to provide medical graduates in large numbers and in the shortest time consistent with reasonably good preparation. Much has been said about maintenance of teaching and hospital staffs, but comparatively little attention has been given to the directors of departments. The departmental head is a leader in all the work of his division; often he exercises an influence in the conduct of associated sectors in the university. Some directors of medical departments have been able to accept assignment to military and other governmental duties because a competent assistant can substitute adequately. The departmental heads who remain often do so because a satisfactory understudy is not available. Among those who remain at their posts, death and disability take their toll at the same rate in war as in peace, and replacement becomes a matter of serious and often urgent moment. The selection of a new director is just as significant in war as in peace, because the appointment is permanent. Thus the present and the long future of the universities are at stake.

The number of new directors at any given time is not large and probably of little consequence in reference to the number of professional men required for the armed forces. The wide ramifications of education are such that the freedom of choice in selection of faculty members has a bearing on the future of our country only second in importance to victory. A sympathetic understanding of the matter by the military agencies must lead to cooperation. Failure to comprehend these realities may limit the choice of teachers to those physically disqualified for military service, those sadly lacking in desire to serve, those too old to be useful to the government and refugees from foreign oppression. No doubt suitable directors may be found among individuals in these categories. However, common justice and future developments should not permit exclusion from

the list of candidates of those who have elected to serve their country in active service. Zeal for education is the keystone of democracy. This principle should be a guide to all concerned with our nation's welfare. Proper cooperation of military authorities with civilian educators in obtaining release from military duties whenever feasible of those concerned with direction of education in professional schools is fundamental to postwar professional rehabilitation.

Current Comment

TSUTSUGAMUSHI FEVER

Tsutsugamushi fever, called also scrub typhus, mite bite fever, tropical typhus and other names, is endemic in Sumatra, New Guinea, Java, Borneo, Formosa, Japan, Australia and the Federated Malay States. Scrub typhus is acquired on exposure to certain types of vegetation in circumscribed areas of untilled open country and especially land that has been cleared of jungle and has subsequently been overrun with weeds and scrub. The etiologic agent is *Rickettsia orientalis*. This agent is mite born. Corbett¹ points out that the primary pathologic changes include vasculitis and perivasculitis with slight tendency toward thrombus formation. The perivascular extension of the infection involves the parenchyma of various organs, and these changes are reflected in the clinical picture. Lipman and his colleagues² state that the usual incubation period probably varies from four to twenty-one days. Vague complaints of malaise, chilliness, vertigo, headache and insomnia may precede the onset of fever. Physical examination often reveals an eschar at the site of the mite bite. Extensive adenopathy is common and is characteristic. The spleen is frequently but not invariably palpable. By the fifth to the eighth day of the disease the majority of patients have a maculopapular, erythematous rash, involving as a rule the lateral or anterior thorax or abdomen with the extremities least affected and the face not involved at all. The rash lasts about eight to twelve days. The febrile stage may persist up to four weeks, the average duration being seventeen days. Rapid breathing in severe cases accompanied by dyspnea is common. Altered respiratory symptoms with increased respiratory rate is usually out of proportion to the physical findings. The cardiovascular system is profoundly affected by the disease. The pulse rate is usually increased in uncomplicated cases but does not exceed 120 beats per minute; when it becomes more rapid it signifies a grave prognosis as a precursor of myocardial failure. Extrasystoles are common; a soft, blowing apical systolic murmur without any demonstrable clinical or x-ray evidence of cardiac enlargement is also common. In fulminating cases one or more of the following are usually noted: cyanosis, severe dyspnea, profound

1. Corbett, Austin J.: Scrub Typhus, Bull. U. S. Army M. Dept., November 1943.

2. Lipman, Bernard L.; Byron, Robin A., and Casey, Adrian V.: Clinical Survey of Scrub Typhus Fever, Bull. U. S. Army M. Dept., January 1944.

tachycardia, auricular fibrillation, gallop rhythm, pulsus alternans or cardiac dilatation. In 2 of the cases studied by Lipman and his colleagues death resulted from massive pulmonary emboli. Treatment is nonspecific. Military personnel with the disease should receive careful cardiovascular and electrocardiographic study before being returned to full or limited duty. The distribution of this disease in areas now being entered for the first time by our troops makes it imperative that its symptoms be kept clearly in mind.

INTRAVENOUS GELATIN

Hogan¹ in 1915 reported beneficial effects from intravenous injections of gelatin in 6 cases of shock. Hogan's report, according to Amberson, represents the first attempt to use a colloid for infusion. Although the method itself provoked little interest, it stimulated others to experiment with acacia. Because of renewed interest in blood substitutes and in parenteral nitrogenous nutrition, Brunschwig and his associates² attempted to determine in animal experiments and in man whether or not gelatin injected intravenously may be well tolerated and also to determine if gelatin remains inert in the organism or can be metabolized. They found in a limited number of clinical cases that gelatin is well tolerated when injected intravenously, that this tolerance extends to repeated, delayed injections and that hypersensitivity does not develop. They also observed that gelatin injected intravenously is at least partly catabolized, since increased urea nitrogen excretion usually obtains when such injections are made. The authors call attention to the fact that gelatin alone is not an adequate source of nitrogen for nutritional purposes because it does not include all essential amino acids. These experiments suggest that intravenous injection of gelatin may be utilized as a method of administering nitrogen. The authors warn, however, that gelatins vary widely in character, depending on the source and method of manufacture. Therefore the results reported cannot be applied to all types of gelatin.

ORAL VACCINES FOR COLDS

Recent communications to the offices of the American Medical Association indicate that the prescription and sale of cold vaccines is again taking place on a large scale. This, in the face of the recognized lack of scientific evidence for the value of these preparations, is indication of irresponsibility on the part of some manufacturers of pharmaceuticals. The scientific evidence against the value of oral cold vaccines is overwhelming; consequently individual physicians and firms who deal in pharmaceuticals and who lend themselves to wholesale uncontrolled distribution of such preparations are perpetrating an unwarranted commercial assault on the public pocketbook.

PHYSIOLOGIC NONSENSE AND POLIOMYELITIS

Since the demonstration of the value of the treatment of poliomyelitis described by Miss Kenny, studies have been made in an attempt to explain the physiologic and pathologic conditions associated with the observed effects. The adherents of the Kenny theory have asserted that the harm of infantile paralysis is due to "spasm" of the affected muscles rather than to a flaccid paralysis. Qualified investigators¹ have shown that this is not the case. As stated recently by Cobb,² it is being demonstrated once more in the history of medicine that new and empirical methods of treatment backed by uncritical enthusiasm may produce many cures but much physiologic nonsense. The treatment may be good, but the ex post facto conclusions of the therapist are usually bad.

EMERGENCY MATERNITY AND INFANT CARE PROGRAM

In the Organization Section in this issue of *THE JOURNAL* appears a statement from the Children's Bureau of the United States Department of Labor indicating the regulations that have been prescribed for those rendering emergency maternity and infant care for the wives and babies of enlisted men. Simultaneously a leaflet has been mailed to every woman receiving dependency allowance informing her that wives of enlisted men are entitled to medical, nursing and hospital care as needed and available through pregnancy, childbirth and six weeks thereafter, that the infants are entitled to similar care until they are 1 year old and that the payments are made by state health departments directly to doctors and hospitals. The leaflet indicates further that the wife may apply for maternity care as soon as she knows she is pregnant and for care for her baby at any time by filling out an application which she gets from the doctor, hospital, clinic, health department, Red Cross chapter or the state health department. The doctor who is to give the care signs the application, which is then forwarded by either the wife or the doctor to the state health department. Services of a consulting physician as needed and available may be provided under the program. In the Organization Section of *THE JOURNAL* last week appeared an extended discussion of this subject before the Annual Conference of Secretaries and Editors of Constituent State Medical Associations. Some of the difficulties already apparent in the situation were emphasized. Many physicians expressed the fear that this was but the entering wedge for a government system of medical service. The appropriation under which this service is provided is distinctly an emergency war appropriation. Further modifications or extensions of this procedure should be considered by the medical profession in the light of their relationship to the practice of medicine now and in the future.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeons General of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession.

ARMY

AVIATION MEDICINE

(Condensed from the Report of the Commanding General of the Army Air Forces to the Secretary of War)

One of the most important tasks of the Air Surgeon's office is setting the physical and psychologic standards for the selection of young men for flight training, and the proper classification of the men as bombardiers, pilots and navigators. This is accomplished by utilizing batteries of tests from which a combined aptitude score is obtained.

When an airplane goes from one theater to another it is carefully inspected so that it does not transport germs or disease-carrying insects.

Calculating the medical and dental supplies needed in all war theaters—for jungle, desert, mountain and arctic operations—is another task of the Air Surgeon. During the past fiscal year the Air Surgeon's office has coordinated the development and purchase of several hundred thousand aeronautic first aid kits, Navy type first aid kits for life rafts, airplane ambulance chests, and frying pan kits which are placed in the seat of the flier's parachute. The frying pan kits contain amphetamine for the temporary relief of fatigue, halazone for chlorinating water, atabrine for malaria, boric acid ointment for burns, sulfadiazine to prevent infection, iodine swabs, salt tablets, bandages, needle and thread, soap for washing, and tea tablets for a warming cup.

Still another task of the Air Surgeon is directing the air evacuation of wounded men. Since Pearl Harbor, over 125,000 casualties (sick, wounded and injured) have been flown from combat zones in American transport planes. This simple statement encompasses one of the greatest accomplishments of modern aviation medicine—an accomplishment of interest to every parent of a soldier in any branch of the Army.

The first obstacle that had to be surmounted in developing the air evacuation service was the supposed danger of killing the patient—estimated by some medical authorities to be a real one in the case of head, chest, spine and internal injuries. Yet the safety of transporting wounded by air has been demonstrated beyond doubt. In the Mediterranean theater from the beginning of the Tunisian campaign in November 1942 to the close of the Sicilian campaign in September 1943 more than 25,000 men with all types of illnesses and wounds were transported 8,000,000 miles by air. Only 1 patient died, 1 in 25,000.

The second obstacle was the shortage of air transports. Airplanes, it was said, could not be spared solely for such purposes. This obstacle was surmounted by the simple conversion of cargo planes carrying troops and supplies to the front to the transportation of patients on the return trip to the rear. Air evacuation is a boon to the morale of ground troops and aids the theater commander by quick removal from the battle zone of his noneffectives. Trips which would take weeks by hospital train or ship are now flown, in a day. Air evacuation is an impressive example of successful cooperation among Army air, ground and service forces.

Flight nurses are carefully selected and trained in phases of aerial medicine, intravenous therapy, tropical medicine, field sanitation, compass, map and aerial photography orientation, what to do in case of air and gas attacks, and other matters. The lives of the men may depend on the proficiency of a flight nurse. Besides looking after the comfort and needs of the sick and wounded men the nurse can also be helpful in maintaining the high morale. Each patient requires individual attention. The nurses of the Army Air Forces have met the tests of battle in a manner to merit unqualified approval.

Complete hospital service now moves with the mobility of war itself. Six days after the Army hospital in Nome, Alaska, burned down a new and complete 25 bed hospital had been flown in from a distance of 3,400 miles. Two field hospitals were flown over the Owen Stanley Mountains in New Guinea. In Sicily a 50 bed hospital was moved by air a distance of 44 miles in two and one-half hours from the time it was dismantled until the time it began receiving patients at the new site.

In designing P-47 Thunderbolt fighters, which maneuver at 400 miles an hour, and Flying Fortress bombers, which can climb to 40,000 feet altitude, aeronautical engineers have carried aircraft performance far beyond the natural tolerance limits of the human body. To make their planes humanly as well as technically practicable the engineers have formed a close partnership with medical scientists.

The main oxygen engineering achievement of the last two years has been the production of the demand type oxygen system, replacing the continuous flow type still found in the older planes. The demand system automatically supplies the flier the amount of oxygen he needs at any altitude up to 40,000 feet. All flying personnel are given indoctrination in the use of oxygen by high altitude training units equipped with low pressure chambers. These units make simulated flights to 38,000 feet, and the necessity of rigid oxygen discipline at high altitudes is made clear to every airman.

Constant research is being done on flying fatigue. Rest camps have been established in theaters of operation and in the United States. In all our active units the flight surgeons keep a close eye on all personnel to discover those men who need a change or rest before the severe demands of combat flying result in serious psychologic maladjustments.

The Convalescent Training Program, which was begun with our men in training, is now being extended to fliers overseas. It stems from a program carried out in the 239 Army Air Force hospitals in this country during the past year. The rehabilitation program includes physical exercises, which may begin in bed and end with outdoor games, and educational pursuits of a vocational or military nature. About 2,500,000 man hours each month are devoted to such activities in the Army Air Forces.

With the intention of achieving equal results in the rehabilitation of the wounded, sick and war weary men, the Army Air Forces are establishing seven rehabilitation centers in the United States. Every known facility is being used to aid these physically and psychologically wounded soldiers to make a new place for themselves in military or civilian life. Our interest and responsibility do not stop at the moment our men drop their bombs on the target.

SHARP INCREASE IN RESPIRATORY DISEASES IN THE ARMY

The War Department recently announced a sharp increase in respiratory diseases in the army similar to that reported among the civilian population of the United States, beginning about November 20 in the Sixth Service Command, which includes the states of Illinois, Wisconsin and Michigan. Current reports, however, indicate that the epidemic is subsiding in this area, but in the South and Southwest, where the outbreak came more recently, the incidence continues to rise.

There has been no increase in the number of cases of pneumonia, and only one death due to influenza has been reported. There were 48,490 cases of common respiratory infections,

including influenza, reported in the army in the continental United States during the week ended December 4, and approximately 150,000 cases during the week of December 11, which compares favorably with the incidence rate reported among the civilian population. The medical department of the army, aided by the Board for the Investigation and Control of influenza, is carefully watching the situation. The Influenza Commission of the board has established laboratories at strategic points throughout the country to observe epidemics, check for the presence of the true influenza virus and inform the Office of the Surgeon General. The War Department has already made plans to assist in furnishing emergency hospitalization, drugs and medical care to stricken areas in the event of an influenza epidemic of really serious proportions.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

FEDERAL FUNDS FOR RELOCATION OF PHYSICIANS

Preliminary steps have been taken to make effective the authority recently granted by Congress to the Public Health Service to provide financial aid to civilian physicians who will agree to relocate to critical areas. Herewith is reproduced a letter sent to all state health officers by the service, under date of January 12, concerning the program. A similar letter has been sent by the Central Office, Procurement and Assignment Service, to all state chairmen of the Procurement and Assignment Service. It is understood that the details of the program will be worked out in the near future. The letter follows:

"Public Law #216, 78th Congress, approved by the President on December 23, 1943, appropriates to the United States Public Health Service the sum of two hundred thousand dollars (\$200,000) during the fiscal year ending June 30, 1944 for the relocation of private practicing physicians and dentists. This act provides in part as follows:

"Provided, That the Surgeon General is authorized on application of a municipality, county or other local subdivision of government duly approved by the state health department having jurisdiction over said municipality, county or other local subdivision of government to enter into agreements with private practicing physicians and dentists under which, in consideration of the payment to them of a relocation allowance of not to exceed \$250 per month for three months and the actual cost of travel and transportation of the physician or dentist and his family and household effects to the new location, such physician or dentist will agree to move to and engage in the practice of his profession in such area for a period of not less than one year; Provided, however, that no such contract shall be made with any physician or dentist unless such physician or dentist shall be admitted to practice by the state authority having jurisdiction of such new location; Provided, further, That each such applicant subdivision shall contribute 25 per centum to the total cost of such relocation allowance, travel and transportation costs of each such physician or dentist and his family obtained by said applicant."

"It is to be noted that this act provides:

"1. That a municipality, county or other local subdivision of government may submit an application to the Surgeon General for the relocation of a private practicing physician or dentist in the applicant subdivision.

"2. That such application must be duly approved by the State Health Department having jurisdiction over said municipality, county or other local subdivision of government.

"3. That the Surgeon General on receiving such application is authorized to enter into an agreement with a private practicing physician or dentist under which, in consideration of a relocation allowance of not to exceed \$250 per month for three months and the actual cost of travel and transportation of the physician or dentist and his family and household effects to the new location, such physician or dentist agrees to move to and engage in the practice of his profession in the applicant subdivision for a period of not less than one year.

"4. That no such contract shall be made with any physician or dentist unless such physician or dentist shall be admitted to practice by the state authority having jurisdiction of such new location.

"5. That each such applicant subdivision shall contribute 25 per centum to the total cost of such relocation allowance, travel and transportation costs of each such physician or dentist and his family obtained by such applicant.

"The State Procurement and Assignment Service has already determined that certain areas in your state are in need of additional physicians and/or dentists. A list of such areas is

ARMY PERSONAL

Col. Manfred U. Prescott, formerly of San Francisco, has been appointed post surgeon and senior medical officer at the Scott Field (Illinois) Army Air Forces Training Command radio school. He will succeed Col. Edwin L. Brackney, who has been transferred to another base. Dr. Prescott graduated from the University of Illinois College of Medicine in 1923 and for the next five years practiced medicine in Chicago and taught anatomy and surgery at the University of Illinois. He joined the medical reserve as a lieutenant in 1925 and was promoted to captain in 1929 and to major in 1935. He was called to active duty with the Army in June 1941 with the rank of lieutenant colonel.

attached. It will be helpful to the Public Health Service if you, in consultation with state chairman, Procurement and Assignment Service, will reexamine these areas as to their present status. If the need exists it is suggested that you rate them in order of urgency. Possibly the areas listed do not include all the needy communities in your state and others may have been brought to your attention which should be added.

"While the state health officer must approve the application from any community made under this act, the State Procurement and Assignment Service chairman has the responsibility of determining which physicians (or dentists) are available for relocation.

"Detailed information together with application forms for use by subdivisions wishing to apply for the relocation of physicians and dentists will be forwarded to you in the near future.

"Similar letters are being sent by the Central Board, Procurement and Assignment Service, to the chairmen of the State Procurement and Assignment Service advising them of the availability of these funds for relocation purposes.

"Your cooperation is solicited in bringing this legislation to the attention of eligible communities."

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quotas allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, January 15, p. 167)

MASSACHUSETTS

Memorial Hospital, Worcester. Capacity, 215; admissions, 7,347. Dr. Winthrop B. Osgood, Superintendent (2 interns).

NEW JERSEY

Holy Name Hospital, Teaneck. Capacity, 226; admissions, 4,843. Dr. F. C. McCormack, Medical Director (5 interns).
St. Mary's Hospital, Orange. Capacity, 160; admissions, 3,742. Sister M. Antoinette, Superintendent (interns).

NEW YORK

Jewish Hospital, Brooklyn. Capacity, 661; admissions, 13,892. Dr. M. Hinenburg, Executive Director (assistant resident—pathology).

NORTH CAROLINA

Watts Hospital, Durham. Capacity, 225; admissions, 5,821. Mr. Sample B. Forbus, Superintendent (residents—medicine, urology).

OHIO

Good Samaritan Hospital, Dayton. Capacity, 350; admissions, 7,999. Sister Frances Maria, Administrator (2 interns, 2 residents).

PENNSYLVANIA

Mercy Hospital, Altoona. Capacity, 180; admissions, 3,867. Mother M. Otillia, Superintendent (interns).
South Side Hospital, Pittsburgh. Capacity, 225; admissions, 5,227. Miss Gertrude L. Heatley, R.N., Superintendent (interns).

TENNESSEE

Nashville General Hospital, Nashville. Capacity, 305; admissions, 6,138. Mr. W. Dortch Wood, Hospital Administrator (3 interns, 1 resident—medicine).

WASHINGTON

Pierce County Hospital, Tacoma. Capacity, 239; admissions, 2,776. Dr. Burton A. Brown, Medical Superintendent (interns).

MISCELLANEOUS

RECOMMENDATIONS OF NATIONAL
RESEARCH COUNCIL RESTRICT-
ING USE OF QUINIDINE

An acute shortage of quinidine exists in the United States today, and possibilities for replacement of present supplies are negligible. It is imperative, therefore, to reduce the use of this important drug and to limit its employment to the treatment of certain cardiac arrhythmias in which experience has shown it to be of special, often critical, value. The problem of conserving supplies of quinidine has been studied by the Committee on Drugs and Medical Supplies of the National Research Council and its Subcommittee on Essential Drugs and by the Committee on Medicine and its Subcommittee on Cardiovascular Diseases. The following recommendations have been made:

It is recommended that quinidine be limited to the treatment of heart disease on prescription of a person licensed to practice medicine and surgery in the state. That this quinidine is to be used for the treatment of heart disease should be certified by the prescribing physician.

It is further recommended that quinidine should not be combined with other drugs and prepared fixed formulas.

Criteria for the use of quinidine during the period of shortage should be limited to:

1. Ventricular tachycardia diagnosed electrocardiographically.
2. Congestive heart failure that appears definitely to have been precipitated by the sudden onset of auricular fibrillation (if not adequately controlled by digitalis).
3. Persistent premature ventricular contractions in patients who have had acute coronary artery occlusion.
4. Chronic disease of the heart associated with paroxysmal auricular fibrillation, paroxysmal auricular tachycardia or auricular flutter.
5. A history of systemic embolization in a case of paroxysmal or established auricular fibrillation.

Prescription of quinidine should be limited to not more than fifty 3 grain tablets for any acute attack of arrhythmia fulfilling one of the foregoing criteria, and to not more than thirty 3 grain tablets per week for the purpose of maintaining sinus rhythm after quinidine has reestablished it.

WARTIME GRADUATE MEDICAL
MEETINGS

Additional subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

At Camp Shanks, Orangeburg, N. Y.: Management of Peripheral Nerve Injuries, Dr. Bronson S. Ray, March 2; Treatment of Anorectal Diseases in the Army, Dr. Frank C. Yeomans, March 16; Fractures, Dr. Clay Ray Murray, March 30.

At Camp Upton, New York: Disordered Action Heart, Dr. B. S. Oppenheimer, February 7; Deficiency States and Their Recognition, Dr. H. D. Kruse, February 14.

At the Mason General Hospital, New York: Disordered Action Heart, Dr. B. S. Oppenheimer, February 7; Deficiency States and Their Recognition, Dr. H. D. Kruse, February 14.

PERSONNEL NEEDED

The Budget Bureau, after due consideration of the growing seriousness of personnel shortages at the Veterans Administration, has granted the veterans' agency an A-1 personnel priority so as to increase its ability to meet growing activities caused by war conditions and loss of personnel. This action of the Budget Bureau places the Veterans Administration in the same priority category as the War and Navy departments in ability to recruit personnel which are necessary to meet present shortages and to permit the expansion required by its growing obligations to the veterans and their families.

The Veterans Administration with increased responsibilities has lost over 6,200 of its personnel to the armed forces—more than 25 per cent of the male employees—in spite of its greater volume of work, caused by the discharge of men from the armed services. General Hines expressed the hope that thousands of veterans who have been discharged from service in the present

war will apply for the vacant jobs, thus rendering assistance to their comrades and families. About 1,000 such veterans have already been appointed in the Veterans Administration, but there is need for many more. An expansion of rating boards, which determine the character of a veteran's disability and make the award of pensions, has been in progress for some time. Doctors, rating specialists and occupational specialists are needed for key positions on these boards.

There has been an acute shortage in hospital attendants, making necessary the detail of more than 1,000 soldiers from the Army to aid in meeting this emergency. Stenographers and clerical workers are also in great demand. Applications for jobs outside Washington should be made to the manager of the nearest Veterans Administration Facility or field station.

CHANGE IN MAIL RULES FOR
PRISONERS OF WAR

Parcels for prisoners of war held in camps in this country should be addressed to the camps, according to Ernest J. Kruetgen, Chicago postmaster. In the past they have been addressed "Via New York."

Letters or cards to camps either in this country or in enemy occupied countries should be continued to be addressed to New York. Postmaster Kruetgen also said that when the name of the addressee is near the top of the envelop the cancellation may obliterate the writing. The addressee's name and address should be placed in the lower right hand portion of the envelop.

Air mail service to prisoners of war in Europe is available at the rate of 30 cents for each half ounce or fraction. This does not include Italy, where no service is available.

OPA ANNOUNCES NEW CEILING PRICES
OF EAR AND ULCER SYRINGES

The Office of Price Administration announced recently reductions in the ceiling prices of ear and ulcer syringes and double end bulbs made of neoprene. Previously all neoprene double end bulbs and ear and ulcer syringes had differentials of natural rubber bulbs of 5 cents each, regardless of size. The new differentials are 3 cents each for such bulbs and syringes under 3 ounces in size, and 4 cents for the 3 ounce size. The differential of 5 cents each is continued for the 4 ounce size of these bulbs. These prices will remain in effect until June 30, 1944.

HEALTH UNDER HITLER

It is reported from Paris that Scapini has given details to the press concerning the replacement of doctors, dentists and chemists in prisoners' camps which started in July 1942, according to the November 13 Vichy Home Service. More than 500 members of the three professions have already gone to Germany, in part replacement of 900. The return of those sent a year ago, to replace their comrades, has to be provided for. Because of these difficulties the authorities have decided to appeal to the Corps de Santé civil to complete the replacement. This corps numbered 30,000 practitioners before the war and can offer efficient help in this work of comradeship. Emphasis was laid on the moral character of this undertaking.

L'Action française of Nov. 20, 1943 (France) states that, after long research, Borsakovski, an engineer, succeeded in incorporating into wheat flour an intermediate husk, very rich in vitamins, diastases and mineral salts, the separation of which from the outer purely cellulose, valueless and indigestible husk has been up till now impossible. Despite present difficulties Jean Couturier, a miller at Montbrisen (Loire), has altered existing equipment and installed new machines. The new flour, which is 97 per cent assimilable, gave excellent results in sanatoriums on a feeding up diet. By decision of the minister of health, the flour thus produced by Couturier is reserved for hospitals, maternity homes and sanatoriums pending large scale manufacture.

ORGANIZATION SECTION

OFFICIAL NOTES

SIXTH ANNUAL CONGRESS ON INDUSTRIAL HEALTH

The sixth Annual Congress on Industrial Health, sponsored by the Council on Industrial Health of the American Medical Association, will be held Tuesday and Wednesday, February 15 and 16, at the Palmer House in Chicago. This meeting follows directly after that of the Congress on Medical Education and Licensure. Physicians and others interested in industrial health are cordially invited. There is no registration fee. The preliminary program is as follows:

TUESDAY, FEBRUARY 15—OPENING SESSION, 10 A. M.

Report of the Council on Industrial Health

STANLEY J. SEEGER, M.D., Chairman, Texarkana, Texas

Industrial Health—A Restatement of Objectives

JAMES E. PAULLIN, M.D., Atlanta, Ga.

President, American Medical Association

Preventive Medicine—Its Importance in Medical Education and Practice

JAMES STEVENS SIMMONS, Brigadier General, M. C., Washington, D. C.

Chief, Preventive Medicine Division of Office of Surgeon General, U. S. Army

Panel—Postwar Industrial Health

Moderator—R. L. SENSENICH, M.D., South Bend, Ind.

Participants:

HARVEY BARTLE, M.D., Philadelphia

Council on Industrial Health

President, American Association of Industrial Physicians and Surgeons

SIDNEY R. GARFIELD, M.D., Oakland, Calif.

Permanent Foundation Hospital

W. P. JACOB, Long Island City

National Association of Manufacturers

NEVILLE PILLING, Chicago

Zurich Insurance Companies

J. G. TOWNSEND, M.D., Bethesda, Md.

U. S. Public Health Service

ROBERT J. WATT, Washington, D. C.

International Representative, American Federation of Labor

BALLROOM

TUESDAY—AFTERNOON SESSION, 2 O'CLOCK

New Developments in Occupational Medicine—Aviation

DAVID N. W. GRANT, Major General, Washington, D. C.

The Air Surgeon, U. S. Army

An Institute of Industrial Health—Plans of a Proposed Development in the Medical Science Center of Wayne University

EDGAR H. NORRIS, M.D., Detroit

Dean, Wayne University College of Medicine

A Visual Service for Small Manufacturing Plants

HARRY S. GRADLE, M.D., Chicago

Medicine, Labor and Industry Join Hands in Philadelphia

CHARLES-FRANCIS LONG, M.D., Philadelphia

Chairman, Commission on Industrial Health and Hygiene, Medical Society of the State of Pennsylvania

The Conquest of Tuberculosis in Industry

HERMAN E. HILLEBOE, Washington, D. C.

Senior Surgeon, Medical Officer in Charge, Tuberculosis Control Section, States Relations Division, U. S. Public Health Service

BALLROOM

TUESDAY—EVENING SESSION, 6:30 O'CLOCK

STATE SOCIETIES DINNER AND ROUND TABLE

An informal dinner and round table discussion intended primarily for the personnel of committees on industrial health in state and county medical societies, will be held.

CRYSTAL ROOM

WEDNESDAY, FEBRUARY 16—MORNING SESSION,

9:30 O'CLOCK

The New Movement in Industrial Sanitation

•MOHE E. SOLWORTH, Louisville, Ky.

Sanitation Consultant

Health Education for Industrial Workers

W. W. BAUER, M.D., Chicago

Director, Bureau of Health Education, A. M. A.

Maladjustment in Industry

FRANK F. TALLMAN, M.D., Lansing Mich.

Director of Mental Hygiene, State Hospital Commission

The Story of Penicillin

CHESTER S. KEEFER, M.D., Boston

Chairman, Committee on Chemotherapy and Other Agents, Division of Medical Sciences, National Research Council

The Detection and Treatment of Malnutrition Among Industrial Workers

TOM D. SPIES, M.D., Cincinnati

Associate Professor of Medicine, University of Cincinnati College of Medicine

BALLROOM

WEDNESDAY, FEBRUARY 16—MORNING SESSION, 9:30 O'CLOCK

SYMPOSIUM ON MEDICAL SERVICE UNDER WORKMEN'S COMPENSATION

Medical Developments in Workmen's Compensation—1943

J. W. HOLLOWAY JR., Chicago

Director, Bureau of Legal Medicine and Legislation, A. M. A.

The Interdependent Problems of the Administrator and the Industrial Physician

MRS. EMMA SANBORN TOUSANT, Boston

President, International Association of Industrial Accident Boards and Commissions

Disability Evaluation—The Solution in Wisconsin

VOYTA WRABETZ, Madison, Wis.

Chairman, Industrial Commission of Wisconsin

Is the Present System of Occupational Disease Coverage Adequate?

RUTHERFORD T. JOHNSTONE, M.D., Los Angeles

Second Injury Funds

J. DEWEY DORSETT, New York City

Assistant General Manager, Association of Casualty and Surety Executives

Supervising Standards of Medical Service for the Injured Workman

D. J. GALBRAITH, M.D., Toronto

Vice Chairman, Ontario Workmen's Compensation Board

CRYSTAL ROOM

WEDNESDAY—AFTERNOON SESSION, 2 O'CLOCK

SYMPOSIUM ON THE REHABILITATION AND REEMPLOYMENT OF THE DISABLED

The Present Status of Rehabilitation in the U. S. Army

FRED W. RANKIN, Brigadier General, U. S. Army, Washington, D. C.

Chief Consultant in Surgery

W. E. BARTON, Major, M. C., Washington, D. C.

Director, Reconditioning Division

Vocational Training and Placement of the Veteran

FRANK T. HINES, Brigadier General, Washington, D. C.

Administrator, Veterans Administration

State Plans for Rehabilitation

MICHAEL J. SHORTLEY, Washington, D. C.

Director, Office of Vocational Rehabilitation, F. S. A.

The Place of the Compensation Insurance Carrier in the Field of Rehabilitation

B. E. KUECHLE, Wausau, Wis.

Vice President and Claim Manager, Employers Mutual Liability Insurance Company of Wisconsin

Current Developments Affecting the Physician's Role in Manpower Utilization

CLIFFORD KUH, M.D., Richmond, Calif.

Permanent Hospitals, Kaiser Shipyards

BERT HANMAN, San Francisco

Regional Staff, War Manpower Commission

Community Organization for Rehabilitation and Reemployment

HAROLD VONACHEN, M.D., Peoria, Ill.

Medical Director, Caterpillar Tractor Company

BALLROOM

WEDNESDAY—AFTERNOON SESSION, 2 O'CLOCK

SYMPOSIUM ON WOMEN IN INDUSTRY

(Arranged by the Committee on the Health of Women in Industry, Section on Obstetrics and Gynecology, American Medical Association)

Report of the Committee on the Health of Women in Industry

H. CLOSE HESSELTINE, M.D., Chicago

Chairman, Committee on Health of Women in Industry

Protection for Industrial Women—Progress and Prospects

MISS MARY ANDERSON, Washington, D. C.

Director, Women's Bureau, U. S. Department of Labor

Why Do Women Stay Away from Work?

C. O. SAPPINGTON, M.D., Dr.P.H., Chicago

Industrial Health Consultant

A Practical Industrial Health Program for Women

FRED B. WISHARD, M.D., Anderson, Ind.

Medical Director, Delco-Remy Division, General Motors Corporation

Discussion Leaders:

FREDERICK H. FALLS, M.D., Chicago

Professor of Obstetrics and Gynecology, University of Illinois College of Medicine

JENNINGS C. LITZENBERG, M.D., Minneapolis

Professor Emeritus Obstetrics and Gynecology, University of Minnesota Medical School

GOODRICH C. SCHAUFFLER, M.D., Portland, Ore.

Associate Clinical Professor of Obstetrics and Gynecology, University of Oregon Medical School

CRYSTAL ROOM

EMERGENCY MATERNITY AND INFANT CARE PROGRAM

Statement of Administrative Policies

The following statement of administrative policies, as revised in December 1943, has been prepared by the Children's Bureau for the information of the state health agencies administering emergency maternity and infant care programs and of individuals or other agencies concerned with the provision of services under this program.

The Children's Bureau will use these policies as the basis for approval of the related portions of state emergency maternity and infant care plans for the fiscal year 1945, and of revisions, amendments or supplements to emergency maternity and infant care plans received during the remainder of the fiscal year 1944. State health agencies may amend their emergency maternity and infant care plans now or at any time during the current fiscal year in accordance with these revised policies.

The administrative policies of the Children's Bureau have been developed within the framework of the Congressional acts and the regulations of the Secretary of Labor, and in accordance with the intent of Congress as shown by the legislative history and interpreted by the bureau and by the Solicitor of the Department of Labor. In the light of the experience of the state health agencies and with the advice of the bureau's professional advisory committees, many modifications of policy have been made. Recommendations made at the conference of official representatives of the servicemen and of medical organizations, held at the Children's Bureau on Dec. 10 and 11, 1943, have been considered carefully in reaching decisions as to these policies. A supplemental statement of policy will be issued on health supervision of infants after further conferences with administrative agencies (see Note, Health Supervision of Infants) and, as experience indicates, on other subjects.

I. INDIVIDUALS FOR WHOM EMIC SERVICES MAY BE AUTHORIZED

1. Any woman applying for care whose husband, at the time of initial application,¹ was in the 4th, 5th, 6th or 7th pay grade of the United States Army, Navy, Marine Corps or Coast Guard (including enlisted men in these grades who are deceased or missing in action).

2. Any infant under 1 year of age for whom an application¹ is made whose father at the time of application was in the 4th, 5th, 6th or 7th pay grade of the United States Army, Navy, Marine Corps or Coast Guard (including men in these grades who are deceased or missing in action).

II. CONDITIONS UNDER WHICH SERVICES MAY BE AUTHORIZED

1. The individual for whom services are authorized is the wife or infant of an enlisted man in the 4th, 5th, 6th or 7th pay grade of the armed forces of the United States.

2. There shall be no financial investigation or means test to determine eligibility as a condition of receiving any service provided under the EMIC program.

3. Similar service is not readily available (without financial investigation and without cost to the patient) from the medical personnel or hospitals of the United States Army, Navy or Public Health Service or from clinics or conferences or other services provided by or through state or local public health agencies or services available under state crippled children's programs.

4. The wife of an enlisted man may have free choice under the program of all types of available facilities and services, including private practitioners, clinics, hospitals and other health facilities that meet the standards established under a state plan for each type of service or facility.

5. The attending physician has the qualifications, and the hospital meets the standards established under the state plan.

6. The attending physician or clinic has agreed to accept payment only from the state health agency for whatever medical or surgical services he renders during pregnancy, labor and six weeks post partum or for the care of an infant for which

authorization has been issued under the state program. (See section IV for types of service that may be authorized.)

7. The hospital, if hospital care is requested, has agreed to accept payment only from the state health agency for services rendered during a period of authorized hospital care under the program and will agree to provide at least ten days' care following delivery if accommodations are available and if the patient wishes to remain in the hospital.

8. The hospital will provide whatever accommodations are indicated by the patient's medical condition at the per diem-rate paid by the state health agency.

9. Physicians' services will not be authorized if the patient or some one in behalf of the patient is to pay for hospital care; and hospital care will not be authorized if the patient or some one in behalf of the patient is to pay the physician for medical care.

10. The cost of medical services in a clinic and/or hospital, including maintenance and salaries, where such medical service is provided by staff physicians (such as interns, resident staff and attending physicians employed full time or part time by the clinic or hospital or other physicians supervising or assisting interns or resident physicians) must be included in the cost per clinic visit and the hospital cost per patient day as outlined in the Children's Bureau memorandum of Sept. 1, 1943, "Purchase of Hospital Care Under Programs for Maternal and Child Health and Crippled Children."

11. Individuals accepted for care under the program will be referred routinely to local public health agencies for the provision of public health-nursing services that can be made available.

12. Arrangements will be made to utilize community facilities, including appropriate social and health agencies, to meet the needs of mothers and infants that cannot be provided under the EMIC program.

DISCUSSION

The emergency maternity and infant care program has been established to provide maternity and infant care to the wives and infants of enlisted men in the four lower pay grades regardless of where they are living, through the development of an organized plan, under the jurisdiction of the state health agency, with a view to making the care provided under the Congressional act available and accessible to all wives who wish to apply for their own care or care of their infants.

The emergency maternity and infant care program is to supplement and not to replace existing facilities for care, which may be available without cost and without financial investigation to enlisted men's wives or infants.

The Congress has made it clear that the care is to be provided as a service to which the wife and infant of an enlisted man are entitled without financial investigation, and that the program is intended to provide the care, if requested by or for the wife or infant of any enlisted man in the four lower pay grades, in order to relieve the enlisted man and his wife of any uncertainty as to how the cost of care will be met and to assure them that care will be provided.

The quality of care should be the best available. To help accomplish this the state health agencies must establish standards for the selection of physicians, nurses, hospitals and clinics providing care, make available consultation services by specialists and other special services, wherever available, and endeavor in every manner possible to maintain recognized high standards of care for mother and child. Quality of care implies that the fullest possible consideration be given to the needs of each patient and that all community resources be mobilized to meet social as well as medical needs.

In order to relieve the enlisted man and his wife of all anxiety with regard to how the cost of care will be met, the state agency, when authorizing medical or hospital care, assumes full responsibility for the payment for such services in accordance with the rates established under the program.

If a physician were to request authorization for hospital care under the program and arrange with the patient to pay him for her medical care, or if he were to request authorization for medical care when the patient is to pay for hospital care, or if a physician or hospital were to charge the patient an amount in addition to that paid by the state agency, it would nullify the Congressional objective of providing care without cost to the enlisted man or his family.

1. If an enlisted man in one of the four lower pay grades, for whose wife or infant application for care has been made, is discharged or promoted after the date of application, or his wife or infant moves to another state or changes physicians, his wife or infant can continue to receive services available under the plan. For purpose of eligibility, the date of application is the date when an application for care is received by the state (or local) health agency, whether on official forms or by letter or by telephone. If application was made by telephone, the date of application is the date when such application was made according to the records of the state (or local) health agency.

III. APPLICATION AND AUTHORIZATION FOR CARE

A. *Application for Care.*²—1. For Maternity Care: Since the wife is entitled, under the program, to complete maternity care, application for care should be made by her or in her behalf as early in pregnancy as possible, directly to the state or local health agency on forms provided for the purpose, or, in an emergency, by letter or telephone.

2. For Infant Care: Similarly, application for care of the infant should be made by the mother, or other person in behalf of the infant, as soon as medical care is needed, preferably at the first visit to physician, clinic or hospital.

NOTE.—On receipt of the application, whether complete or incomplete, the state (or local) health agency should assume responsibility for planning for local services and care as needed by the applicant.

DISCUSSION

The Emergency Maternity and Infant Care Program is not simply the payment for services needed but a plan whereby the state and local health agencies assist the families of enlisted men in obtaining the medical, nursing, hospital and other services needed for maternity care of their wives and medical care of their infants, seeking the support of all community resources in meeting these needs and maintaining the highest possible standards of care. Many of these families are unfamiliar with the resources for health and other services in the community in which they are now residing. The earlier the state and local health agencies are aware of the needs of each of these families, the better they can assist them in obtaining services needed. Early application for maternity care is therefore desirable, and every possible means should be used to inform the public about the program and to encourage wives and physicians to get applications in early.

B. *Authorization for Care.*—1. For Maternity Care: The wife should enter on the application form the date during pregnancy when she first requested care under the emergency maternity and infant care program from this physician, clinic or hospital.

The physician's statement on the application blank constitutes a "request for authorization" for the care outlined by him on the blank. Whenever possible the blank should be filled in and dated at the visit when the wife first applies to him for care under the program. The physician should check, if possible, the husband's serial number and military rank or rating, as entered on the patient's part of the form with her allowance card, letter or other information.

The wife should be responsible for sending the completed blank to the state (or local) health agency.

The "effective date of authorization" (the date from which the state health agency assumes responsibility for payment for services) shall be: The date during pregnancy when the wife first requested care under the emergency maternity and infant care program from physician, clinic or hospital; provided the application, signed by the physician, is received by the state or local health agency within six weeks after the date when the wife first requested care under the program. If not received within six weeks after the wife first requested care under the program, the "effective date of authorization" shall be a date not more than six weeks prior to the date when the application, signed by the physician, was received in the state (or local) health agency.

In cases in which the wife has made one or more visits to the physician, clinic or hospital before she requests care under the program, and the application, signed by the physician, is received by the state health agency late in the wife's pregnancy, the "effective date of authorization" may be an earlier date than has been defined to cover previous visits, provided a statement is submitted to the state (or local) health agency in writing that (1) establishes an acceptable reason for delay in application, such as misinformation, misunderstanding of procedure or other valid reason, (2) indicates the amount of care pre-

2. Application blanks and full information about the program should be available readily in physicians' offices, clinics, hospitals, Red Cross chapters, local health and welfare agencies, and from local public health nurses. Application blanks have two parts: (1) the wife's statement and (2) the physician's statement. On obtaining a blank the wife should fill out her part, take it to a physician (in office or clinic) and ask him to fill out his part. She should then send it herself immediately to the state (or local) health agency. The date when the application, including the physician's statement, is received at the state (or local) health agency is important in establishing the date when the cost of care is assumed by the state health agency. However, even though prompt completion of the application is important, the wife should not delay sending in her part of the application if for some reason the physician's statement cannot be filled out at once or other information cannot be obtained. In this case a second application blank must be used by the physician when he fills out his request for authorization.

viously given and (3) shows that no payment has been made to the physician by or in behalf of the wife for care during the period covered by the authorization.

Application for delivery care received after the date of delivery should be approved for authorization only when supported by information indicating a medical emergency, such as a premature delivery, or a situation beyond the control of the patient, such as delay in mails, misunderstanding of procedures, misinformation or other valid reason.

2. For Infant Care: The physician's statement on the application blank constitutes his request for authorization to give care to the infant as outlined by him on the blank. The blank should be filled in and dated during, or as soon as possible after, the first visit of, or to, a sick infant. The physician should check, if possible, the husband's serial number and military rank or rating, as entered on the patient's part of the form, with her allowance card, letter or other information.

The mother, or other person applying in behalf of the infant, should be responsible for sending the completed blank to the state (or local) health agency.

The "effective date of authorization" for medical care of a sick infant shall be the date when the physician or clinic or hospital agreed to give care for the present illness, provided it is not more than ten days prior to the date when the application was received in the state (or local) health agency.

3. Emergency Care: In case of emergency, authorization for care of wife or infant may be given, provided request for authorization of such services is received by letter, telephone or telegraph within a reasonable interval of time, as defined by the state health agency, after the occurrence of the emergency.

IV. SERVICES THAT MAY BE AUTHORIZED BY STATE OR LOCAL HEALTH AGENCIES AND RATES OF PAYMENT

A. *For the Wife.*—1. Medical and Surgical Services Provided by Physicians in Private Practice:³ This includes services to a patient who has sought and received care in the private office of a physician during the antepartum period. For this type of care, payment is to be made directly to the physician by the state health agency.

It also covers services to a patient who has sought and received care in the private practice of a physician employed full time or part time by a medical school, for which payment may be made to the medical school or to the physician depending on the customary procedure for receipt of such payments.

a. Complete maternity care: For "complete maternity care," that is, all services rendered by the attending physician: (1) to the mother during pregnancy, labor and the postpartum period from the effective date of authorization until six weeks after termination of pregnancy, including office treatment of intercurrent conditions whether attributable to pregnancy or not, but excluding home or hospital care of conditions not attributable to pregnancy (as outlined under b and c) and (2) to the infant during the first two weeks of life: The rate of payment as established by the state health agency, but not to exceed \$50.

When fewer than seven antepartum examinations are made, when no postpartum examination is made or when other services recognized as part of routine complete maternity care are omitted, the rate of payment for complete maternity care is to be adjusted to cover only the services actually rendered. When an obstetrician refers an infant to a pediatrician for routine care during the first two weeks of life, no reduction need be made in the rate of payment to the obstetrician for "complete maternity care."

In exceptional cases additional payments for attending physicians' services may be authorized by the state (or local) health agency for continuing care of the mother beyond six weeks post partum for a serious, acute complication resulting from pregnancy, such as puerperal infection.

(For rates of payment see item c).

b. Major nonobstetric intercurrent surgical operations: Additional payments may be authorized by the state (or local) health agency to attending physicians who qualify as consultants (for qualifications of consultants see section IV, 2) in a surgical specialty, for major, nonobstetric surgical operations needed during pregnancy and six weeks post partum for conditions not attributable to pregnancy (such as appendectomy during pregnancy) at a rate established by the state health agency not to exceed a total of \$50 for preoperative, operative and postoperative care.

c. Medical care of other intercurrent nonobstetric conditions: Additional payments for attending physicians' services (for a period of three weeks with review by the state or local health agency before authorizing an extension of care) may be authorized by the state (or local) health agency during pregnancy

3. For services of consulting specialists, see section C, item 1.

and six weeks post partum for the home or hospital treatment of intercurrent conditions not attributable to pregnancy, which do not require major surgery at weekly rates of payment for medical care as established by the state health agency, but not to exceed \$12 for the first week of illness and, if fewer than four home or hospital visits are made during the week, proportionate payment to be made for services rendered; for succeeding weeks of illness not to exceed \$6 a week, and, if fewer than three home or hospital visits are made during a week, proportionate payment to be made for services rendered.

d. Antepartum care only, or spontaneous abortion: When only antepartum care is provided by the attending physician, at a rate of payment established by the state health agency but not to exceed \$15 for care during the antepartum period. If fewer than seven antepartum visits are made, proportionate payment to be made for services rendered.

If pregnancy terminates in spontaneous abortion not requiring an operation, at a rate of payment not to exceed \$15, plus proportionate payment for antepartum visits made.

e. Therapeutic abortions: For therapeutic abortions or spontaneous abortions requiring an operation including preoperative and postoperative care, the rate of payment will not exceed that established by the state health agency for care during labor and six weeks post partum.

f. Ectopic pregnancy: For treatment of ectopic pregnancy including preoperative and postoperative care, when laparotomy is performed by attending physician, rate of payment will not exceed the rate established by the state health agency for "complete maternity care."

g. Care of newborn infant by pediatrician: Routine care of newborn infant for first two weeks by a qualified pediatrician when infant is referred by obstetrician who does not customarily provide routine care of infants, at a rate established by the state health agency not to exceed \$6 per week. If fewer than three visits to the infant per week are made by the pediatrician, proportionate payment to be made for services rendered.

2. Hospital Care During Pregnancy, Labor or Within Six Weeks After Termination of Pregnancy: Authorization may be made for a maximum of fourteen days (with extension of care authorized, when necessary, for two week periods, after review by the state or local health agency) with payment at the "per diem rate" established for payments to the hospital by the state health agency times the number of days' stay in the hospital (in accordance with the Children's Bureau memorandum of Sept. 1, 1943, "Purchase of Hospital Care Under Programs for Maternal and Child Health and Crippled Children").

3. Medical and Surgical Services Provided Through Clinics and Hospitals: When a patient has sought and received care in a clinic or hospital, the payments to the clinic or hospital will cover payments of the cost (including maintenance and salaries) of all medical services provided by interns, residents or other physicians employed part time or full time by the clinic or hospital and by the physicians supervising or assisting the interns or resident physicians, as well as payment for all other services provided by the clinic or hospital, as follows:

a. For clinic services (other than state or local health agency clinics): At rates not to exceed the cost per clinic visit times the number of clinic visits and not to exceed the maximum rate established by the state health agency.

b. For hospital services: The "per diem rate" established for payments to the hospital by the state health agency times the number of days' stay in the hospital (in accordance with the Children's Bureau memorandum of Sept. 1, 1943, "Purchase of Hospital Care Under Program for Maternal and Child Health and Crippled Children").

c. For clinic and hospital service: Many hospitals have an inclusive flat rate covering outpatient and inpatient medical and hospital maternity care. This flat rate may be paid if it does not exceed the total of a and b.

B. For the Infant.—1. Medical and Surgical Services for Sick Infant Provided by Physicians in Private Practice:⁶ This includes care that has been sought on behalf of, and received by, a sick infant in the private practice of a physician (home, hospital or office) during the infant's first year of life. For this type of care payment is to be made directly by the state health agency to the physician. It also covers care sought on behalf of, and received by, a sick infant in the private practice of a physician employed full time or part time by a medical school, payments for which may be made to the medical school or to the physician depending on the customary procedure for the receipt of such payments.

4. No authorization would be issued, nor payments made, for antepartum care given in antepartum clinics conducted by state or local public health agencies. However, authorization for hospital care planned for through such a clinic would be necessary and should be requested by the physician in the clinic.

5. For services of consulting specialists, see section C, item 1.

Medical care may be authorized for a period not to exceed three weeks, with review by the state health agency before authorizing extension of care.

a. Medical care, including minor surgery: At weekly rates established by the state health agency but not to exceed \$12 for the first week of illness, and, if fewer than four visits for examination or treatment are made during the week, proportionate payment to be made for services rendered. For succeeding weeks of illness \$6 and, if fewer than three visits for examination or treatment are made in any week, proportionate payment to be made for services rendered.

b. Major surgery: Additional payments may be authorized by the state health agency to attending physicians who qualify as consultants (for qualifications for consultants see section IV, 2) in a surgical specialty, for major surgical operations performed on infants under their care (exclusive of care for which infants are eligible under state crippled children's programs), at rates of payment to be established by the state health agency but not to exceed a total of \$50 for preoperative, operative and postoperative care.

2. Hospital Care: Hospital care during the first year of life may be authorized for fourteen days (with extension of care authorized, when necessary, for two week periods after review of case by state or local health agency): At the "per diem rate" established for payments to the hospital by the state health agency times the number of days' stay in the hospital (in accordance with the Children's Bureau memorandum of Sept. 1, 1943, "Purchase of Hospital Care Under Programs for Maternal and Child Health and Crippled Children").

3. Medical and Surgical Services Provided Through Clinics and Hospitals: When care of a sick infant has been sought and received in a hospital or clinic, the payments to the clinic or hospital will cover payment for the cost (including maintenance and salaries) for all medical services provided by interns, residents and other physicians employed part time or full time by the clinic or hospital and by physicians supervising or assisting interns or resident physicians, as well as payment for all other services provided by the clinic or hospital, as follows:

a. For clinic services: At a rate not to exceed the cost per clinic visit times the number of clinic visits and not to exceed the maximum rate established by the state health agency.

b. For hospital services: The "per diem rate" established for payments to the hospital by the state health agency times the number of days' stay in the hospital (in accordance with the Children's Bureau memorandum of Sept. 1, 1943, "Purchase of Hospital Care Under Programs for Maternal and Child Health and Crippled Children").

4. Immunizations in Physicians' Offices, at Child Health Conferences or Immunization Clinics Not Conducted by State or Local Health Agencies:⁶ At rates established by the state health agency but not to exceed \$6 total for immunization for smallpox, diphtheria and whooping cough (plus the cost of biologic products in states where these are not provided without cost by the state or local health agencies). These immunizations usually will require, during the first year of life, one procedure for smallpox, two or three for diphtheria and three for whooping cough. If immunizations for all three diseases are not completed, proportionate payment is to be made for services rendered.

NOTE.—Health Supervision of Infants.—In child health conferences: Health supervision of infants may be arranged for in child health conferences made available by state or local health agencies or by voluntary health agencies. For the present, the cost of health supervision through conferences may be met from Maternal and Child Health funds made available under title V, part 1, of the Social Security Act.

Administrative problems relative to the inclusion under the Emergency Maternity and Infant Care program of health supervision of infants in physicians' offices are now being studied by the Children's Bureau and will be reviewed in the near future with state and local officials responsible for the administration of the program. These problems include the desirable minimum requirements of training and experience to be established for physicians providing health supervision of infants and the methods of authorizing and making payments for such supervision provided in physicians' offices. When decisions with respect to payment for health supervision of infants are reached, a supplement to this statement of policy will be issued.

It is recommended, therefore, that authorization for health supervision of infants, except for immunizations, not be given under the Emergency Maternity and Infant Care program until the Children's Bureau policy on these matters has been made available to state administrative agencies.

6. No authorization would be needed, nor payment made, for immunization at child health conferences or immunization clinics conducted by state or local public health agencies.

C. *For the Wife or Infant.*—1. Consultation Services Requested by Attending Physician (from consultants on list approved by the state health agency): a. Long distance telephone consultation: The actual cost of the call.

b. Bedside consultation or assistance or minor surgery: At the rate of payment established by the state health agency but not to exceed \$10 per consultation.

c. Consultation which includes performance of a major surgical operation by the consultant and for the preoperative and postoperative care provided by the consultant: At the rate of payment established by the state health agency but not to exceed \$50.

2. Bedside Nursing Service in Home or Hospital, When Requested by Attending Physician, for Wife or Infant Receiving Care Under EMIC Program: a. In a hospital by graduate nurses: Special nursing services during a period of critical illness when such nursing services cannot be provided by nurses employed by the hospital and when no expenditures for special nursing service have been included in the hospital's annual statement of operating expense may be authorized for a period not to exceed four days, with review by state (or local) health agency before authorizing extension of care, at prevailing local hourly or per diem rates not to exceed maximum rate established by state health agency.

b. In the home by nursing staff of a voluntary public health or visiting nurse agency or by graduate nurses (when such nursing services cannot be made available by state or local public health agencies): (1) Visits for care of mother and infant while the mother is receiving bed care during the puerperium may be authorized not to exceed six visits, with review by state health agency, before authorizing extension of care, at prevailing local rates per visit but not to exceed the maximum rate established by the state health agency.

(2) Visits for care of a sick mother or infant may be authorized not to exceed fourteen visits with review by the state health agency, before authorizing extension of care, at prevailing local rates per visit but not to exceed the maximum rate established by the state health agency.

(3) Nursing care throughout the period of labor and delivery may be authorized at prevailing local rates but not to exceed maximum rate established by state health agency.

(4) Special nursing services on an hourly or per diem basis during a period of critical illness may be authorized for a period not to exceed four days, with review by a state health agency before authorizing extension of care, at prevailing local rates not to exceed the maximum rate established by the state health agency.

(5) Visits for care of a patient who has complications, in order to carry out specific orders by the physician, such as determining blood pressure, urinalysis or giving special treatments or medications may be authorized not to exceed six visits, at prevailing local rates per visit but not to exceed the maximum rate established by the state health agency.

3. Blood for Transfusions: This may be authorized at the customary minimum rate paid by the hospital but not to exceed the maximum rate established by the state health agency.

4. Ambulance Service: When requested by attending physician or hospital, ambulance service may be authorized at prevailing local rates not to exceed the maximum rate established by the state health agency.

5. Additional Payment for Time in Travel and for Cost of Travel to Attending Physician or Consultant: This may be authorized for attending seriously ill patients or for home deliveries, outside of city limits of physician's residence, at rates established by the state health agency, not to exceed 25 cents per mile each way traveled outside the city limits, with maximum payment of \$25 to a physician for travel for any 1 case.

6. Additional Payment for Cost of Travel of Graduate Nurse: Additional payment to a graduate nurse not employed by a public or voluntary health agency to the home of a patient may be allowed at the cost of transportation outside city limits on a public carrier or at the usual rate for mileage established for state employees.

DISCUSSION

The appropriation act for emergency maternity and infant care states that the funds are to be used to provide medical, nursing and hospital maternity and infant care. Review of the discussions in Congress clearly indicates that it has been the intent of Congress to provide as complete and as satisfactory medical, nursing and hospital care during the maternity period and the first year of the infant's life as is possible to obtain. To supplement when necessary the care usually recognized as required for the uncomplicated maternity case or for the sick infant, special additional care needed for complications or serious illness is therefore included under the program. This includes, as neces-

sary, consultation and diagnostic assistance of specialists, which should be made as freely available as possible under the program, prolonged hospital care, special nursing service, and special therapeutic measures such as blood for transfusion when applied for by the attending physician, clinic or hospital during the period when care has been authorized.

Calling a consultant should not affect the rate of payment to the attending physician if he continues to provide care to the patient.

V. QUALIFICATIONS FOR PHYSICIANS AND NURSES PARTICIPATING IN THE PROGRAM

1. *For Obstetric Services.*—Qualifications required of practitioners performing obstetric services under the program shall be established by each state health agency.

2. *For Medical Services Other Than Obstetric.*—Graduates of medical schools approved (at time of graduation or subsequent to graduation) by the Council on Medical Education and Hospitals of the American Medical Association. Individual exceptions may be made when a person with the degree of doctor of medicine who is not a graduate of a medical school approved (at time of graduation or subsequent to graduation) by the Council on Medical Education and Hospitals of the American Medical Association has completed postgraduate training which, in the opinion of the state health officer and his technical advisory committee, makes him competent to participate in this program.

Additional Qualifications for Consultants.—Specialists who are certified by their respective American boards of medical specialties, or whose training and experience meet the requirements of training and experience for admission to the examinations of such boards, should be designated as consultants by the state health departments and, whenever possible, made available for bedside consultation (or telephone consultation when bedside consultation is not feasible) with physicians participating in the plan. Physicians who have had at least one year of graduate training in a residency in their specialty approved by the Council on Medical Education and Hospitals of the American Medical Association and at least one year's experience limited to the practice of the specialty may be designated as assistant consultants.

For areas where consultants with the training and experience as set forth in the preceding paragraph are not available, a state technical advisory committee, appointed by the state health agency for this program, should recommend to the state health agency a plan for providing consultation to patients living in such areas.

Lists of physicians approved by the state health agency as consultants in the various specialties should be made available to all physicians participating in the program.

3. *For Pediatric Services to Newborn Infants Referred by Obstetricians.*—Diplomates of the American Board of Pediatrics or physicians who have completed at least one year of graduate training in a pediatric residency approved by the Council on Medical Education and Hospitals of the American Medical Association.

4. *For Nursing Service Purchased on a Case Basis.*—Graduate nurses registered or eligible for registration by meeting requirements of the state board of nurse examiners and having had training and experience in maternity and/or pediatric nursing as required by the state health agency.

VI. MINIMUM REQUIREMENTS FOR HOSPITALS PARTICIPATING IN PROGRAM

The following represent minimum requirements that will be used by the Children's Bureau in reviewing state plans for approval. A state health department may use them as a basis for preliminary approval of hospitals for obstetric care, but they should not be construed as establishing even minimum standards for such hospitals.

Since in the various states wide differences will be found in hospital facilities available, some state health departments will be able to establish higher requirements than others. Each should develop a set of requirements that are as high as are practicable under existing conditions and should consider the possibility of raising the requirements as soon as possible.

Since in some states it will be practicable to establish minimum requirements that could not be met by many of the hospitals in other states, those requirements which should be considered absolutely minimum for emergency approval under any conditions have been indicated by one star (*), and those which should be established as minimum when conditions permit, either at the time of approval or later, have been indicated by two stars (**).

1. BUILDINGS

- * Obstetric care shall be authorized only in buildings that meet state or local rules and regulations for fire protection and sanitation.
- * Buildings shall be adequately screened to give protection against flies and mosquitoes.
- * Every room in which maternity patients or newborn infants are cared for shall have at least one window to provide light and ventilation (unless forced ventilation is provided).

There is evidence that sunlight passing through ordinary window glass has some bactericidal action. Change of air content of rooms by admitting outdoor air tends to reduce the bacterial content of the air and adds to the patient's comfort.
- * In every room used in the care of maternity patients and newborn infants there shall be artificial lighting adequate for the purposes for which the room is used.
- * There shall be provision for adequately heating the building in cold weather, with maintenance of a fairly uniform temperature in delivery rooms and nurseries.

The shock of labor and delivery for mother and infant make provision of suitable environmental conditions essential. The newborn infant's need for artificial heat after leaving the protection of the uterus is obvious, and chilling may be fatal especially to premature infants.

2. MATERNITY UNIT

- * Maternity patients and newborn infants shall be cared for only in wards or rooms completely separated from other wards or rooms in which patients with communicable diseases or septic conditions are cared for.

The special susceptibility of puerperal women and newborn infants to various types of infection is well known. The danger of cross infection will be less the greater the degree of separation of these patients from all other patients; i. e., in a separate wing, a separate floor or a room or rooms separated by a partition from that section of the hospital in which patients with septic conditions or communicable diseases are cared for.

- ** Maternity patients shall be cared for only in a part of the hospital in which complete separation from all other patients is possible.

a. Facilities for Delivery

- * If there is no delivery room separate from the general operating room, patients shall be delivered in their own rooms except in case of cesarean section. There shall be conveniently located facilities for the attendants at delivery to scrub their hands.

Since the parturient woman is especially susceptible to infection, it is unwise to deliver her in a room used for septic cases regardless of the care with which cleaning of the room is carried out. Hand scrubbing facilities are essential to the use of aseptic technic.
- ** There shall be a properly equipped delivery room used exclusively for the delivery of noninfectious patients. There shall be running water in this room or adjacent to it.
- * There shall be suitable facilities for administering general anesthesia.
- * There shall be suitable apparatus for administering oxygen to infants.
- * A reliable method for identifying each infant shall be applied in the delivery room.

b. Nursing Services

- * A graduate registered nurse shall be responsible at all times for nursing care of both maternity patients and newborn infants.
- ** At least one graduate registered nurse shall be on duty at all times to supervise the care of both maternity patients and newborn infants.

Every puerperal woman and newborn infant needs skilled nursing care. This is essential not only for the normal needs but because of the potential danger to both from infection and hemorrhage and the danger to the infant from asphyxiation.

In addition, the nurse is the person who is responsible throughout the twenty-four hours and will often be required to make decisions vital to the patients' safety (both mother and infant) in absence of the physician.

c. Care of Utensils and Linen

- * There shall be facilities for disinfection or, preferably, sterilization of bedpans.

Contaminated bedpans may be a source of cross infection.

- * There shall be adequate and suitable receptacles for soiled linen (bed linen; gowns and diapers).

Soiled linen may, if not kept in closed containers, be a source for spread of infection.

- ** There shall be a utility room used for maternity patients only.

d. Laboratory and Clinical Facilities

- * There shall be facilities in the hospital or available in the community for laboratory examinations, including blood counting, hemoglobin determinations and urinalyses.
- ** A separate room shall be provided in the hospital for a laboratory.
- * There shall be facilities in the hospital always ready for intravenous therapy.
- ** There shall be serum available in the hospital for blood matching for transfusions.
- * The hospital shall provide adequate facilities for sterilization of equipment, supplies and instruments.

e. Records

- * A clinical record shall be kept for each patient, mother and infant separately.

f. Accommodations for Patients

1. For the mothers:

- * Rooms or wards in which maternity patients are cared for shall provide average space equal to at least 60 square feet per patient.

To provide for adequate ventilation, for space for bedside care of the patient and for separation of the patients sufficient to minimize respiratory cross infections.

- ** Rooms or wards in which maternity patients are cared for shall provide average space equal to at least 80 square feet per patient.

- * There shall be a separate bed for each patient.

- ** There shall be a separate thermometer and a bedpan for each patient.

Handwashing facilities:

- * Running water shall be conveniently available to every room in which maternity patients are cared for.

To facilitate hand washing by staff (medical and nursing) before and after caring for each patient. Hand washing is one of the important measures for prevention of infection. The more convenient the facility, the more likely it is that the hand scrubbing will be done.

- ** Running water shall be available in each room or ward.

Isolation facilities:

- * A room shall be available at all times in which a maternity patient who has an infection may be isolated.

Prevention of spread of infection from 1 patient to another depends on separation of the patient who is suspected of having an infection from noninfected patients and in maintaining rigid separate isolation of the infected patient until cured or, preferably, until discharged from the hospital.

- ** Space shall be available at all times for isolation of at least 1 patient for every 25 obstetric beds or fraction thereof.

Dietary department:

- * Food adequate for the needs of the parturient women shall be prepared and served under sanitary conditions.

- ** If the food service is not under the direction of a qualified dietitian, consultation should be obtained from a dietitian or nutritionist available to the community.

2. For the infants:

-Nursery facilities:

- * If newborn infants are not kept in their mothers' rooms, a separate nursery shall be provided for them, which is used for no purpose other than the care of such infants.

- * Provision shall be made to exclude visitors from contact with infants. If infants are kept in their mothers' rooms, a separate room must be made available in which to place them during visiting hours.

To prevent respiratory infections in newborn infants, they should be isolated from visitors.

- * Each infant shall have a separate bassinets.

In order to minimize the danger of cross infection, 2 infants should never occupy the same bassinets, even if they are twins.

- * Individual bassinets shall be separated by at least 6 inches.

Separation of bassinets is required (1) so that bedclothes from one bassinets will be less likely to come in contact with those on either side and (2) to facilitate bedside care of each infant.

- ** Individual bassinets shall be separated by at least 12 inches.

- * Nurseries shall be large enough to provide an average of at least 16 square feet of floor space per infant.

This is the minimum space that will permit proper spacing of beds (6 inches from walls and 6 inches between beds) and that will provide space for the nurse to care for the infant.

** Nurseries shall be large enough to provide an average of at least 20 square feet of floor space per infant.

* There shall be provided for premature infants at least one incubator or some type of heated bed for each 20 bassinets for full term infants or any fraction thereof.

* There shall be provided in the nursery facilities for washing or disinfecting the hands.

To avoid carrying infection to infants the hands must be carefully washed both before and after caring for each infant.

Isolation for infants:

* There shall always be available a room in which infants who have or who are suspected of having infections may be strictly isolated from the well infants and from one another.

To prevent spread of infection, there should be provision for immediate isolation of any infants suspected of having an infection.

Clinical facilities for infants:

* There shall always be available facilities for oxygen administration suitable for use with infants.

Newborn infants, especially premature infants, are prone to respiratory difficulties. Oxygen administration is essential for combating these difficulties.

* There shall always be available either in the hospital or in the community sterile sets for intravenous or subcutaneous administration of blood or other fluid to infants.

Facilities for preparation of milk mixtures:

* There shall be suitable space and adequate equipment for preparation of milk mixtures (formulas) and for their sterilization and refrigeration.

** There shall be a separate room used exclusively for the preparation of sterile milk mixtures.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—A subcommittee of the Senate Committee on Education and Labor has recommended to the full committee that the Veterans' Education Bill, S. 1509, be reported favorably with certain modifications. A subcommittee of the Senate Committee on Commerce has been conducting hearings on S. 1096, a bill to establish a Bureau of Vital Records in the United States Public Health Service. Several state directors of vital statistics have testified before the subcommittee.

Bills Introduced.—S. 1616, introduced by Senator Wiley, Wisconsin, proposes to make available additional benefits for veterans of World War II in the form of vocational rehabilitation and educational benefits under the direction and supervision of the Administrator of Veterans' Affairs. S. 1633, introduced by Senator Walsh, Massachusetts, at the request of the Navy Department, proposes to amend the nurse training act so as to provide that the head of any department, establishment or other federal agency may request and accept transfers of student nurses, who are transferable under the original act, to a federal hospital operated by his agency in continental United States, exclusive of Alaska, and to provide for the continued training of such student nurses requisite to graduation. The period of training of such transferee may not extend beyond the period required for graduation by the institution from which the student nurse was transferred and may be terminated at any time prior thereto as the interests of the service may require. H. R. 3904, introduced, by request, by Representative Randolph, West Virginia, provides for the detention, care and treatment of persons suffering from diseases of the mind in certain federal reservations. H. R. 3920, introduced by Representative Fernandez, New Mexico, proposes to grant the state of New Mexico new lands for the Tingley Crippled Children's Hospital and for elementary and secondary vocational trade schools. H. R. 3935, introduced by Representative Rogers, Massachusetts, proposes an appropriation of \$500,000,000 to construct additional veterans' hospitals. H. R. 3973, introduced by Representative Rogers, Massachusetts, declares the Veterans' Administration to be an agency of the United States vital and essential to the successful prosecution of the war and entitled, second only to the War and Navy Departments, to priorities in personnel, equipment, supplies and material under any laws, executive orders and regulations pertaining to priorities. The Secretary of War and the Secretary of the Navy will be authorized to transfer any personnel, whether commissioned, enlisted or inducted, from the Army or Navy respectively to the Veterans' Administration, with the proviso that, to the extent practicable, personnel so transferred should be selected from those persons not qualified for general service in combat areas. H. R. 3921, introduced by Representative Rogers, Massachusetts, is similar to H. R. 3973 in granting priorities to the Veterans' Administration but in addition directs the Administrator of Veterans' Affairs and the Federal Board of Hospitalization to expedite and complete the construction of

additional hospital beds for war veterans and to enter into contracts for the use of permanently constructed Army and Navy hospitals by the Veterans' Administration after cessation of hostilities and after such institutions are no longer needed by the armed services.

STATE MEDICAL LEGISLATION

Kentucky

Bill Introduced.—H. 16 proposes to enact a separate naturopathic practice act and to create a board of naturopathic examiners to examine and license applicants for licenses to practice naturopathy. Naturopathy, according to the bill, means "Nature cure or health by natural methods" and is defined as "the prevention, diagnosis and treatment of human injuries, ailments and diseases by means of any one or more of the psychological, physical or mechanical, chemical or material, forces or agencies of Nature." Naturopaths are to be permitted to practice obstetrics if they "first comply with the requirements of the County Board of Health, by taking the required examination and obtaining a midwife license" but they are not to be authorized to "perform any surgical work other than minor matters."

New York

Bills Introduced.—A. 12 proposes so to amend the hospital lien act as to provide specifically that a hospital lien may not be asserted with respect to personal services rendered by any physician or surgeon. S. 9 proposes to enact an optical dispensing act and to create a state board of examiners in optical dispensing to examine and license applicants for licenses to practice optical dispensing, which is defined to embrace the compounding and dispensing of lenses, spectacles, eyeglasses, optical devices or other optical appliances to the intended wearer thereof on written prescriptions from licensed physicians or optometrists for the aid, correction, relief or treatment of visual or ocular anomalies of the human eye.

Rhode Island

Bills Introduced.—H. 560 proposes to extend until the adjournment of the 1945 session of the legislature the life of the special Rhode Island public health laws survey commission authorized by the legislature in 1943. H. 564 proposes to prohibit the manufacture, possession for sale, or sale of stated caustic poisons used as household chemicals unless the containers thereof bear the word POISON in heavy faced caps. The bill also proposes to prohibit the manufacture or sale of ammonia or any chlorinated form of bleaching fluid the label or package of which bears any false or misleading statements, or, in the case of ammonia, which contains less than 8 per cent of actual ammonia, or, in the case of chlorinated bleaching fluid, which contains less than 2¼ per cent of available chlorine. The bill also proposes to prohibit the manufacture and sale of chlorinated bleaching and disinfecting fluids which are artificially colored.

Medical News

(PHYSICIANS WILL CONFIR A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS FILIATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

ARKANSAS

University News.—Recent lecturers at the University of Arkansas School of Medicine, Little Rock, have included Dr. Olympio da Fonseca Jr., Rio de Janeiro, on "Malaria" and "Dermatocomycosis"; Dr. Arnold D. Welch, Glen Olden, Pa., "Recent Advances in Sulfonamide Drugs," and Dr. Irving S. Wright, New York, "Peripheral Vascular Diseases" and "Capillary Studies."

GEORGIA

Changes in the Faculty.—Dr. Robert C. Major has resigned as assistant in surgery at Emory University School of Medicine, Atlanta, to become full time professor of thoracic surgery at the University of Georgia School of Medicine, Augusta, effective January 1. Dr. John Robert Rinker, Fort Worth, has been appointed full time professor of urology at Georgia.

ILLINOIS

Crippled Children Unit in New Home.—The division of services for crippled children of the University of Illinois recently was moved into the Bressmer Home, 1105 South Sixth Street, Springfield. The administrative and accounting offices occupy the first floor, the record and file rooms, the central nursing district office and the conference room the second floor, while the third floor is now used for storage but can be furnished and used for offices if required. The service of the division is carried on through a field staff of orthopedic and public health nurses working out of district offices in Chicago, Peoria, Springfield, Champaign and Mount Vernon. These nurses plan and supervise annually some seventy orthopedic clinics at key cities in the state, which are usually attended by about 2,500 children for diagnostic and follow-up care. When the division was established in 1937 it was a unit of the department of public welfare. At the beginning of the 1941-1942 fiscal year for administrative reasons and in accordance with an agreement between the department of public welfare, the University of Illinois and the commission for handicapped children, the division was placed under the jurisdiction of the university which also administers the Illinois Surgical Institute for Children, a state owned and state supported institution established for the surgical care of children. The division was created as an official state agency under the Federal Social Security Act to extend and improve services for locating crippled children and to provide medical, surgical and corrective facilities for diagnoses, hospitalization and after-care for the children who are crippled or who are suffering from conditions which lead to crippling. Under the setup the division is not able to extend care to persons who have attained their twenty first birthday. A recent development, however, has been the extension of this rule to provide that assistance may be given to persons over 21 who are victims of poliomyelitis. Twenty five thousand dollars of the \$225,000 appropriation recently approved for the current biennium has been earmarked specifically for victims of poliomyelitis without respect to age.

Chicago

Personal.—Miss Elizabeth F. Carr, librarian of the New York Post-Graduate Medical School, Columbia University, New York, has been appointed librarian of the Archibald Church Library of Northwestern University Medical School to succeed Miss Louise Walker, resigned, effective January 1. Miss Carr will begin her new position February 1. —Dr. Rafael Mendez, instructor in pharmacotherapy, Harvard Medical School, Boston, has been appointed assistant professor of pharmacology at the Loyola University School of Medicine.

Lectures on Medical Care.—Dr. Morris Fishbein, Editor of THE JOURNAL, opened a series of lectures on medical care at the University of Illinois College of Medicine, January 12, with a talk entitled "Health of the American People." The series is sponsored by the Student Council of the college of medicine and other lecturers include

Joseph Dean Lohman, A.M., January 26, Health and the Distribution of Medical Care
Dr. Roland R. Cross, Springfield, February 9, Preventive Medicine and Public Health

Dr. Victor Johnson, Secretary to Council on Medical Education and Hospitals, American Medical Association, February 23, Role of Postgraduate Education in Modern Medicine
Dr. Chaucey C. Maher, March 8, Chronic Disease and Its Implications as a Social Problem
Lawrence J. Litch, March 22, Correlation of Medical Services with Governmental Agencies
A. M. Simons, Assistant Director, Bureau of Medical Economics, American Medical Association April 12, Organization of Medical Services in America
Louis Wirth, Ph.D., Plans for Medical Care

INDIANA

Library Collection as Memorial to Dr. Hutchins.—A portion of the library of the late Dr. Frank F. Hutchins has been given by his wife, Mrs. Luella Hutchins, to the University of Indiana Medical Center, Indianapolis, to be set up in a separate library unit as a memorial to the physician who was a member of the medical school for many years. Dr. Hutchins became a member of the faculty of the State College of Physicians and Surgeons when it was organized in 1906, and when the Indiana Medical College was united with the Indiana University School of Medicine in 1908 under the name of the latter he became professor and head of the department of mental and nervous diseases. Dr. Hutchins served as a member of the committee which worked out the organization of the faculty of the two schools after study of the medical schools at Harvard, Johns Hopkins and Pennsylvania universities. He served without compensation as departmental chairman until his retirement in 1938. Dr. Hutchins died in February 1942.

Secretaries' Conference.—The Indiana State Medical Association will conduct its annual secretaries' conference at the Indianapolis Athletic Club, Indianapolis, January 23. The morning session will be devoted to a school for speakers who will talk to lay groups on the Wagner-Murray-Dingell bill, at which Dr. Homer G. Hamer, Indianapolis, will give an outline plan for speakers, Mr. Clarence A. Jackson, Indianapolis, "The ABC's of Social Security", William Norwood Bragance, Ph.D., Crawfordsville, professor of speech, Wabash College, "Making the Speech Count" and Dr. Franklin S. Crockett, Lafayette, "Addressing Local Lay Groups." At the conference in the afternoon, the speakers will include

Dr. Charles N. Combs, Terre Haute, Hospital Plans in Indiana
Dr. Edward J. McCormick, Toledo, Ohio, Public Relations and the Medical Profession
Mr. J. W. Holloway Jr., Chicago, National Legislative Problems
Dis. Norman M. Beatty and Joseph William Wright, Indianapolis, Local Legislative Problems
Dr. Eldridge M. Shanklin, Hammond, Your Part in Making a Better State Medical Journal

IOWA

Dr. Mengert Goes to Southwestern Medical School.—Dr. William F. Mengert, since 1938 associate professor of obstetrics and gynecology at the State University of Iowa College of Medicine, Iowa City, has resigned to become professor and head of the department of obstetrics and gynecology at the Medical School of the Southwestern Medical Foundation, Dallas.

KENTUCKY

Committee Named to Seek Funds for Tuberculosis Sanatoriums.—The Kentucky State Medical Association has appointed a committee of three to present the needs for two tuberculosis sanatoriums in the state in a bill to the legislature asking for appropriations. The members are Drs. Carl Norfleet, Somerset, representing central Kentucky, William Clark Bailly, Harlan, representing eastern Kentucky and Carl C. Howard, Glasgow, representing western Kentucky. The state society will ask the state to appropriate \$500,000 to build two sanatoriums, one in eastern Kentucky and one in western Kentucky and, in addition, \$100,000 for maintaining the institutions for one year after they are built.

LOUISIANA

New Orleans Graduate Medical Assembly.—The eighth annual session of the New Orleans Graduate Medical Assembly will be held March 6-9, at which the following will participate:

Dr. Robert L. Levy, New York, Cardiology
Dr. Carroll S. Wright, Philadelphia, Dermatology
Dr. Walter L. Palmer, Chicago, Gastroenterology
Dr. Robert A. Ross, Durham, N. C., Gynecology
Dr. Ralph H. Major, Kansas City, Mo., Medicine
Dr. Abraham Myerson, Boston, Neurophysiology
Dr. John W. Harris, Madison, Wis., Obstetrics
Dr. H. Winnett Orr, Lincoln, Neb., Orthopedic Surgery
Dr. Chevalier L. Jackson, Philadelphia, Otolaryngology
Dr. Paul R. Cannon, Chicago, Pathology
Dr. Henry G. Poncher, Chicago, Pediatrics
Dr. Louis A. Bute, Rochester, Minn., Proctology
Comdr. Lewis Kraer Ferguson (MC), U. S. Naval Reserve, Surgery
Dr. George T. Pack, New York, Surgery
Dr. Frank Hinman, San Francisco, Urology

MICHIGAN

Annual Clinic Day.—Mount Carmel Mercy Hospital, Detroit, will conduct its annual clinic day on January 26. Dr. Louis J. Gariepy, chief of staff, and Dr. Edward Dowdle will open the program. Other speakers will include:

- Dr. Harold Henderson, Detroit, The Role of the Cervix in Obstetrics.
- Dr. Joseph L. DeCoursey, Cincinnati, Riedel's Struma Disease of the Thyroid Gland.
- Dr. Fredrick F. Yonkman, Detroit, Some Recent Advances in Therapeutics.
- Dr. Charles M. McKenna, Chicago, Interesting Anomalies of Genito-urinary Tract.
- Dr. Norman Charles Bender, Buffalo, Meningitis in Children.
- Dr. Thomas E. Jones, Cleveland, Cancer of the Colon.
- Dr. Robert A. Hittig, Ann Arbor, Tropical Diseases and Their Relation to the Postwar Period in the United States.
- Drs. Frederick A. Collier and Cyrus C. Sturgis, Ann Arbor, Newer Concepts, Diagnosis and Management of Diseases of the Liver.

At a luncheon meeting the speakers will be Drs. Eugene C. Keyes, Dearborn, Edgar H. Norris, Detroit, and Claude R. Keyport, Grayling.

Secretaries' Conference and School of Information.—A feature of the annual secretaries' conference of the Michigan State Medical Society at the Book-Cadillac Hotel, Detroit, January 30, will be a school of information to discuss trends in the regimentation of medicine. The speakers will be Mr. J. W. Holloway Jr., Chicago, Dr. L. Fernald Foster, Bay City, Dr. Robert L. Novy, Detroit, and Mr. William J. Burns, Lansing. Other speakers on the program will be Dr. Edward J. McCormick, Toledo, Ohio, "Need for Public Relations," and Floyd E. Armstrong, A.M., Cambridge, Mass., "Bureaucracy as It Affects Medicine." "Information to the Public," presented by Mr. Thomas A. Hendricks, Indianapolis, and Paul D. Bagwell, M.A., East Lansing, will be discussed by Dr. G. Lombard Kelly, Chicago, Secretary, Council on Medical Service and Public Relations of the American Medical Association. An exhibit entitled American Medicine and Medical Service, prepared by Thomas G. Hull, Ph.D., Chicago, will be displayed during the meeting.

NEW YORK

Graduate Instruction.—Dr. Ralph G. Stillman, assistant professor of medicine (clinical pathology), Cornell University Medical College, will deliver a graduate lecture on "The Significance of Laboratory Tests and Methods in the Practice of Medicine" before the Suffolk County Medical Society, January 26, in Patchogue.

New York City

Lectures for the Public.—On February 3 a series of medical lectures will be opened by members of the faculty of Long Island College of Medicine, Brooklyn, for lay members of the Society of the Friends of the College and their guests. Dr. Jean A. Curran, president and dean of the medical school, will give an address and Arnold H. Eggerth, Ph.D., associate professor of bacteriology, will discuss "Penicillin Research." Others in the series will be:

- Dr. Howard W. Potter, February 10, War Nerves.
- Dr. Alfred C. Beck, February 17, The Birth of a Baby.
- Dr. Elberton J. Tiffany, February 24, Tropical Diseases, War and Postwar Aspects.
- Dr. Phillips F. Greene, March 2, On China's Medical Front.

Medical Education in Relation to the Practice of Medicine.—A symposium on medical education in relation to the practice of medicine of the future opened at the New York University College of Medicine, January 17, to continue weekly until February 21. Dr. Alan Gregg, medical director of the Rockefeller Foundation, gave the first lecture on "Looking to the Future." Other speakers will be:

- Leonard Carmichael, LL.D., Medford, Mass., January 24, The Relation Between Medical and Premedical Education.
- Joseph W. Mountin, assistant surgeon general, U. S. Public Health Service, January 31, Public Health in the Future Medical Curriculum.
- Dr. Louis Hamman, Baltimore, February 7, The Place of Psychiatry in the Teaching of Clinical Medicine.
- Dr. Franz Goldmann, New Haven, Conn., February 14, Instruction in Social and Economic Aspects of Medicine.
- Dr. Adam D. Macdonald, Manchester, England, February 21, Medical Education in Britain After the War.

Forum for Clinical Research.—The New York Academy of Medicine announced a forum for the first week of April in which research workers of the city and vicinity may present results of original research in clinical medicine. Presentations will be limited to twelve minutes. A brief period of free discussion will follow each presentation. The publication of presentations is not a necessary condition, but the academy plans to publish in its bulletin abstracts of presentations if the author so desires. The fact that material has in substance or

in part been presented elsewhere will not be regarded as a bar to presentation, provided the work represents recent research. The committee extends an invitation to all research workers of Greater New York and of neighboring cities within a radius of 100 miles to submit an abstract, not to exceed two hundred words in length, of proposed presentation to the secretary of the committee on medical education of the academy not later than March 1. A formal invitation will then be extended by the committee to the authors of papers selected for presentation to participate in this program.

Changes in Faculty at Long Island.—Recent promotions on the faculty at Long Island College of Medicine, Brooklyn, include:

- Dr. Thomas D. Dublin to professor of preventive medicine and community health.
- Dr. Edwin P. Maynard Jr. to professor of clinical medicine.
- George Samuelsen to assistant professor of chemistry.
- Dr. George E. Anderson to clinical professor of medicine.
- Dr. C. Thomas Chiamonte to assistant clinical professor of dermatology and syphilology.
- Dr. Walter A. Coakley to clinical professor of plastic and maxillofacial surgery.
- Nicholas B. Dreyer, M.A., to professor of pharmacology.
- Dr. Arthur E. Lamb to assistant clinical professor of medicine.
- Dr. Dorothy Loomis to assistant professor of pathology.
- Dr. A. W. Martin Marino to assistant clinical professor of surgery.
- George H. Paff, Ph.D., to associate professor of anatomy.
- Dr. John M. Pearce to associate professor of pathology.
- Dr. Howard W. Potter to professor of clinical psychiatry.
- Dr. Ainsworth L. Smith to assistant clinical professor of surgery.

Dr. Phillips Foster Greene, professor of surgery at the Hsiang Ya Medical College, Changsha, China, has been appointed visiting professor of surgery, effective from Dec. 1, 1943 to July 1, 1944. Dr. Matthew Gerard Golden was appointed assistant clinical professor of otolaryngology and Dr. Walter Mochle clinical professor of ophthalmology.

OHIO

The Rachford Lectures.—Dr. William E. Ladd, William E. Ladd professor of child surgery, Harvard Medical School, Boston, presented the twelfth annual series of the Benjamin Knox Rachford Lectures, January 18-19. His subjects were "Surgical Manifestations of Congenital Malformations of the Alimentary Tract" and "Experiences with Esophageal Atresia and Tracheoesophageal Fistulas." The Rachford lectureships were established as a memorial to Dr. B. K. Rachford because of his work in the physiology of digestion and other scientific investigations, his organization of the pediatric department of the University of Cincinnati College of Medicine and his leadership in providing medical care for underprivileged infants and children of the community and through the Babies Milk Fund Association.

Commission for Study of State Institutions.—Governor John W. Bricker has named a committee to study conditions and needs in all state mental institutions and to make recommendations regarding them to the governor and the state department of public welfare. Members of the new committee are Dr. George T. Harding, Columbus, councilor for the Tenth District of the state medical association; Leonard W. Mayo, dean of the School of Social Sciences, Western Reserve University, Cleveland; Dr. Arthur T. Hopwood, medical superintendent of the Institution for Feeble-minded, Apple Creek; Probate Judge Charles Chittenden, Toledo; William W. Greulich, Ph.D., head of the department of anatomy, Western Reserve University, Cleveland; Hal Griswold, Cleveland, attorney and former state welfare director, and Bleecker Marquette, executive secretary of the Public Health Foundation, Cincinnati.

Industrial Health and the Doctor.—The theme of a series of industrial health conferences to be presented in February under the auspices of the state medical association and the state department of health will be "Industrial Health and the Doctor." A similar program will be presented at each of the four centers: February 7 Toledo, Toledo Academy of Medicine Auditorium, February 8 Cleveland, Hotel Cleveland, February 9 Columbus, Deshler-Wallick Hotel, and February 10 Cincinnati, Netherland Plaza Hotel. The speakers will include:

- Dr. Carey P. McCord, medical consultant, Chrysler Corporation, Detroit.
- Dr. Frank F. Tallman, Lansing, director of mental hygiene, Michigan State Hospital Commission.
- Dr. Rutherford T. Johnstone, director, department of occupational diseases, Golden State Hospital, Los Angeles.

One hour at the afternoon session will be devoted to short informal discussions of the practical aspects of local industrial health problems, the role which the medical society should take and the responsibilities and obligations, as well as the opportunities, of the individual physician in industrial medicine and industrial health.

OKLAHOMA

Changes in the Faculty.—Mrs. Mildred T. Gossett, for years secretary to Major General Robert U. Patterson, M. C., U. S. Army, retired, formerly dean of the University of Oklahoma School of Medicine, Oklahoma City, has been appointed executive secretary of the medical school. Other changes on the faculty include:

John Walter Barnard, Ph.D., to assistant professor of anatomy.
Kenneth M. Richter, Ph.D., to assistant professor of histology and embryology.
Dr. Jack L. Valin to assistant professor of anesthesiology.
Dr. John W. Cavanaugh to assistant professor of surgery.
Dr. John F. Hackler to professor of hygiene and public health.
J. Allan Stanley, Ph.D., to assistant professor of physiology.
Dr. Noble Franklin Wynn to instructor in pharmacology (part time).

Samuel A. Corson, Ph.D., has resigned as assistant professor of physiology.

OREGON

Tuberculosis Program.—Dr. William R. Murlin has been lent by the U. S. Public Health Service to serve as acting director of the division of tuberculosis control of the Oregon State Board of Health. One of the recent activities of the department is an x-ray case finding program among industrial workers in Portland.

Changes in Health Officers.—Rudolph R. Lang, passed assistant surgeon, U. S. Public Health Service, was assigned as health officer of Deschutes County, succeeding Dr. Frederick P. Rogers, who is entering military service.—Dr. Louie A. Maulding, Nyssa, has been appointed health officer of Malheur, succeeding Dr. Clyde R. Walker, resigned.

PENNSYLVANIA

Physician Observes Ninety-Seventh Birthday.—Dr. Louis H. Gibbs, Scranton, who started to practice in West Scranton in 1878, observed his 97th birthday, December 22. He graduated at the Bellevue Hospital Medical College, New York, in 1873.

Philadelphia

Dr. Reeves Named Director of Health.—Dr. Rufus S. Reeves has been appointed director of health for a four year term to succeed Dr. Hubley R. Owen. Dr. Reeves took office January 3. As a part of his program Dr. Reeves announces the introduction of a series of weekly radio health broadcasts to educate the public to better health and appointed the following to serve as chairmen of the advisory committees to cooperate in the project:

Dr. Henry L. R. Bockus, stomach and intestinal diseases.
Dr. Frank A. Craig, tuberculosis.
Dr. Damaso de Ruvas, glandular diseases.
Dr. Charles W. Dunn, glands of internal secretion.
Dr. Harrison F. Flippin, pneumonia.
Dr. Sigmund S. Greenbaum, social hygiene.
Dr. Robert H. Ivy, plastic surgery.
Dr. Chevalier L. Jackson, bronchoscopic diseases.
Dr. Virgil H. Moon, laboratory studies.
Dr. John Royal Moore, bone and joint diseases.
Charles Patton, D.D.S., dentistry.
Dr. Frederic H. Leavitt, nervous and mental diseases.
Dr. Walter I. Lillie, diseases of the eye.
Dr. Charles F. Long, industrial medicine.
Dr. Samuel A. Loewenberg, internal medicine.
Dr. Clifford B. Lull, gynecology and obstetrics.
Dr. John D. McLean, public health.
Dr. Sarah I. Morris, preventive medicine.
Dr. Ralph M. Tyson, children's diseases.
Dr. Horace J. Williams, diseases of the ear, nose and throat.
Dr. Carroll S. Wright, diseases of the skin.
Dr. Ralph Pemberton, rheumatic diseases.
Dr. Alexander Randall, diseases of the urinary tract.
Dr. Thomas A. Shallow, surgery.
Dr. Anthony Sindoni Jr., diabetes.
Dr. Bernard P. Widmann, x-ray studies.
Dr. Michael G. Wohl, nutrition.
Dr. Charles C. Wolferth, diseases of the heart and blood vessels.

SOUTH CAROLINA

Public Health Election.—Dr. John Claude Sease, Little Mountain, was chosen president-elect of the South Carolina Public Health Association at its recent annual meeting in Columbia and Dr. George S. T. Peeples, Columbia, was installed as president. Mrs. Frank George, R.N., Columbia, is the secretary-treasurer.

Society Entertains Honorary Members.—The Greenville County Medical Society held a banquet on January 3 to pay tribute to its honorary members: Drs. Curran B. Earle and Chesley T. J. Giles, Greenville, Frederick G. James Greer, James W. Jervey and Fletcher Jordan, Greenville, Lawrence L. Richardson, Simpsonville, and Edward C. Stroud, Marietta. Dr. Wyatt Y. McDaniel, Taylors, also a honorary member, was unable to attend because of illness.

GENERAL

Red Cross Appeals for Funds.—The American National Red Cross announced that its appeal for funds will be conducted during the month of March, designated by President Roosevelt as Red Cross Month. In a release the Red Cross states that during 1944 it must supply some five million blood donations and each month during the year must recruit 2,500 nurses for the army and navy.

Medical Record Dedicated to Max Neuburger.—The *Medical Record* for December was dedicated to Dr. Max Neuburger, commemorating his seventy-fifth anniversary. Dr. Neuburger has been associated since 1939 with the Wellcome Historical Medical Museum, London. He formerly served as professor of the history of medicine at the University of Vienna and founded there the Institute for Medical History and Museum.

Slide Film Talkie on Public Health Service.—The Zurich General Accident and Liability Insurance Company has prepared a slide film talkie descriptive of the work of the U. S. Public Health Service and of the various state and county health departments. Copies have been sent to the health officers of the forty-eight states and the District of Columbia for their use. It is proposed to give wide distribution to the picture with a view to acquainting the American public with the health facilities available.

Examinations in Obstetrics and Gynecology.—The dates for the part II examination of the American Board of Obstetrics and Gynecology, to be held in the Hotel William Penn, Pittsburgh, have been changed from June 9-14 to June 7-13. The written examination and review of case histories (part I) for all candidates will be held in various cities in the United States and Canada, February 12. Additional information may be obtained from Dr. Paul Titus, secretary of the board, 1015 Highland Building, Pittsburgh 6.

Appointments to National Chamber of Commerce.—Dr. Leverett D. Bristol, executive director of the Hospital Council of Greater New York, has been appointed chairman of the health advisory council of the Chamber of Commerce of the United States, succeeding Dr. James S. McLester, Birmingham, Ala., who continues as a member of the council but who relinquishes the general chairmanship because of his increasing activity in the war service of the federal government and the state of Alabama. Dr. Anthony J. Lanza, chief of the occupational hygiene section of the Office of the Surgeon General, U. S. Army, has been named chairman of the council's committee on industrial health to succeed Dr. Bristol. Dr. McLester is a former president of the American Medical Association. Dr. Bristol and Dr. Lanza are members of the Council on Industrial Health of the American Medical Association.

Civilian Medicine to Gain from Progress in War Medicine.—A survey just concluded by the Johnson and Johnson Research Foundation, New Brunswick, N. J., indicates that substantial gains in civilian medicine will follow the conclusion of the war. A report states that "out of this war so far have come new therapeutic agents, new methods for treating shock, for preventing infections and healing wounds. New anesthetics are being used and new surgical skills are being developed." The world's many war theaters in effect are huge medical clinics where doctors in special fields accomplish results that might require years in peacetime. The new medical knowledge they are obtaining will be beneficial in days to come in preventing disease, in fighting infection, in treating accident victims and in such projects as opening up the tropics to human habitation at a higher standard of living. They will have a wide and beneficial application in civilian medicine, it was stated. This study discloses that the American medical profession, in cooperation with the surgeons general of the services, is striving constantly to shorten the lag between the development of new wartime medical discoveries and their application to those who need them.

Special Society Elections.—Anton J. Carlson, Ph.D., emeritus professor of physiology of the University of Chicago School of Medicine, has been elected president of the American Association for the Advancement of Science. Forest R. Moulton, Ph.D., Washington, D. C., is the permanent secretary. —The American Society of Anesthetists announces the following officers, among others, chosen at its annual election Dec. 9, 1943: Drs. Emery A. Roventine, New York, president; Ralph M. Waters, Madison, Wis., president-elect; Leo V. Hand, Boston, Hugh O. Brown, Chicago, and Kenneth Heard, Toronto, Canada, vice presidents; McKinnie L. Phelps, New York, secretary, John G. Dunlop, Los Angeles, assistant secretary; Virginia Appgar, New York, treasurer, and Elisha

D. Embree, Houston, Texas, assistant treasurer. Dr. Albert J. Erdmann Jr., New York, one of the original founders of the Long Island Society of Anesthetists (which later became the New York Society and still later the American Society) and one of the pioneers in the field of anesthesia, attended and spoke briefly at this meeting.—Warren F. Draper, assistant surgeon general, U. S. Public Health Service, Washington, D. C., was chosen president-elect of the Association of Military Surgeons of the United States at its annual meeting in October, and Col. Lucius A. Salisbury, National Guard, Scarsdale, N. Y., was inducted into the presidency. Col. James M. Phalen, M. C., U. S. Army, retired, Washington, is the secretary. The next annual meeting will be in New York, November 2-4.

Mortality Among Children with Rheumatic Fever.—Children with rheumatic fever are subject to a very high mortality during the acute phase of the disease, but once this stage is passed the death rate falls sharply, according to the *Statistical Bulletin* of the Metropolitan Life Insurance Company in reviewing a study of 2,817 policyholders of the company under age 20 who received nursing care between 1936 and 1938 by the company's visiting nurse service during an acute attack of the disease and have been followed up each year since. The study covers the group up to 1942. Of the group 257, or 1 out of every 11, have died, giving a mortality about fifteen times as high as would be expected in a group of young persons of like sex and age distribution. The death rate among the boys has been about one-fifth greater than among the girls. In a group of children who were definitely reported to have heart involvement during the attack there occurred 152, or nearly 60 per cent of all the deaths. The bulletin points out that since there is some degree of heart involvement in practically every attack of rheumatic fever, whether or not reported, it may be concluded that cases in which a heart condition was actually reported represent the most severe in the study. Nearly one fifth died in the first year following the acute attack in the group with reported heart involvement. The actual death rate was 184 per thousand each year as compared with 23 per thousand in the second year and an average of 16 in the subsequent period of observation. In contrast, the bulletin states, a death rate of little more than 1 per thousand has prevailed among children of these ages in the general experience of the company. Among the group reported without heart involvement, the death rate in the first year was 18 per thousand, 11 per thousand in the second year and an average of 7 per thousand during the remaining period. Heart disease was reported as the cause of 80 per cent of the deaths among the children in the study. According to the bulletin the majority of the cardiac deaths were due to rheumatic heart disease. Particular interest is attached to the high incidence of subacute bacterial endocarditis. Among the children studied there were 26 deaths from this cause, or 13 per cent of the total from heart disease. Older children were principally affected, 21 of these 26 deaths being recorded among those 10 years or older at first observation, whereas only a little more than half of the cases in the study were in this age group. There were 38 deaths in the group attributed to infectious diseases, with 18 charged to pneumonia. The bulletin points out that the study clearly indicates seriousness of rheumatic fever in childhood, stating that the disease is now a leading cause of disability and death in the school ages and in adults up to middle life.

CANADA

Society News.—The British Columbia Medical Association at its annual meeting recently choose the following officers: Drs. Philip A. C. Cousland, Victoria, president; Allen Y. McNair, Vancouver, Andrew H. Meneely, Nanaimo, vice presidents; Gordon O. Matthews, Vancouver, honorary secretary. —Dr. I. Newton Kugelmass, New York, gave the postgraduate fortnightly address at the University of Montreal, October 5, on "Blood Diseases in Children." He addressed the Montreal Medical Society the same day on "Early Recognition of Nutritional Deficiencies in Children."

CORRECTIONS

Gm. Instead of Mg.—In THE JOURNAL, Dec. 25, 1943, page 1115, in the article by Merrill, in the second column, under Conclusions, in the fifth line, 0.24 mg. should have been 0.24 Gm.

Tracheotomy in Bulbar Poliomyelitis.—In the article by Dr. T. C. Galloway in THE JOURNAL, Dec. 25, 1943, page 1096, the word "centimeter" at the end of the fifth line of the first case report and at the end of the fourth line in the report of case 3 should read "millimeter."

Government Services

New Supervisor of War Public Services

Mrs. Dorothy S. Bauman has been named supervisor of War Public Services for the Federal Works Agency in region I, comprising the New England states, New York, New Jersey and Pennsylvania. Mrs. Bauman "will supervise child care activities, including war nurseries and centers for before and after school care of young children of mothers in war essential jobs, and extended hospital and community services attributable to the war impact." Coincident with this announcement was one that \$500,000 had been allotted by the Federal Works Agency to New York City for the conversion of a part of Bellevue Hospital and the convalescent camp in Welfare Island, New York, for the treatment and control of venereal diseases.

Hospital Men Volunteers

The Office of Civilian Defense and the American Hospital Association are cooperating in a program to organize hospital men volunteers to remedy the shortage of nonprofessional male personnel in hospitals. A leaflet has been issued containing suggestions for forming this service. Additional information may be obtained from "Volunteer Aide Services in Hospitals," published by the United Hospital Fund, 370 Lexington Avenue, New York, "Volunteers in Health, Medical Care and Nursing," published by the Office of Civilian Defense (available from the local defense council), and the preliminary report of the Committee on Volunteer Workers, Council on Association Development, entitled "Guide for the Use of Volunteer Service in Hospitals" (available from the American Hospital Association, 18 East Division Street, Chicago).

Examination for Assistant Surgeon and Passed Assistant Surgeon

The U. S. Public Health Service announces an examination for appointment to the grade of assistant surgeon and passed assistant surgeon in the regular corps of the service. Applicants for assistant surgeon must not have passed their 32d birthday, and applicants for the grade of passed assistant surgeon must not have passed their 39th birthday on the date the written examination is begun. All applicants must be citizens of the United States, graduates of a class A medical college, and must have completed or will complete by July 1 next at least one year of internship or its equivalent. Allowances are made for internships under the accelerated training program. The compensation of officers in the grade of assistant surgeon, both regular and reserve corps, is \$3,411 per annum with dependents and \$2,975.50 per annum without dependents. The compensation of officers in the grade of passed assistant surgeon, both regular and reserve corps, is \$3,991 per annum with dependents and \$3,555.50 per annum without dependents. The board of examiners will be in the following places at 9 a. m. on the dates specified. Candidates should arrange to have their physical examination completed and prepare their autobiographies at any one of the following listed places just prior to the date shown:

U. S. Marine Hospital, Staten Island, N. Y.	January 31
U. S. Marine Hospital, Boston.	February 3
U. S. Marine Hospital, Baltimore.	February 7
U. S. P. H. S. Dispensary, 4th and D Sts. S.W., Washington, D. C.	February 9
U. S. Marine Hospital, Norfolk, Va.	February 11
U. S. Marine Hospital, Cleveland.	February 15
U. S. Marine Hospital, Chicago.	February 17
Office of Indian Affairs, 218 Federal Building, Minneapolis.	February 19
U. S. Marine Hospital, Seattle.	February 23
U. S. Marine Hospital, San Francisco.	February 28
U. S. P. H. S. Relief Station, 406 Federal Building, Los Angeles.	March 3
U. S. P. H. S. District No. 8, 617 Colorado Building, 16th and California Sts., Denver.	March 6
U. S. Marine Hospital, Kirkwood, Mo.	March 9
U. S. Marine Hospital, Louisville, Ky.	March 11
U. S. Public Health Service Hospital, Fort Worth, Texas.	March 17
U. S. Marine Hospital, Galveston, Texas.	March 20
U. S. Marine Hospital, New Orleans.	March 22
Malaria Control in War Areas Office, 605 Volunteer Building, Atlanta, Ga.	March 25
U. S. P. H. S. Relief Station, 365 Federal Building, Miami, Fla.	March 28
U. S. P. H. S. Dispensary, 4th and D Sts. S.W., Washington, D. C.	April 4

Application blanks may be obtained from the Surgeon General, U. S. Public Health Service, Washington 14, D. C. (Bethesda Station).

Nutrition in Enemy Occupied Europe

At the Royal Society of Medicine a discussion took place on nutrition in enemy occupied Europe. An appalling picture was presented. Col. W. E. Vignal said that the daily ration in France yielded only 1,084 calories and was deficient in fat, protein and sugar. Tuberculosis was increasing alarmingly, and the Germans were enforcing complete silence about it. They had returned to France many tuberculous prisoners, most of them urgently needing treatment. Increasing numbers of workmen were returning from Germany to die of tuberculosis after a few months work there. France was now largely deprived of her sanatoriums and supplies, and patients had to wait six or eight months for treatment in institutions. Acute bronchopneumonic types were common, and so was rapid wasting ending in death. Many suffered from progressive asthenia and severe malnutrition. The condition of children was even more alarming. They showed a high incidence of tuberculosis. Ninety per cent of one group studied were 2 to 9 Kg. under weight. The physiologist Richet had been imprisoned for saying that 10 million persons were suffering from hunger and 2 million were likely to die.

Dr. A. P. Cawadias described famine conditions in Greece. Well to do people in Athens had 1 ounce of bread on alternate days, camomile tea and gruel, with oil and carrots and chicory coffee. Sausages of dog, rat and cat were sold at outrageous prices. The mortality was terrible; they had ceased to bother about tuberculosis, but now the incidence of malaria was 100 per cent in endemic areas, and hunger edema and other nutritional diseases were spreading.

Prof. J. Young quoted a paper by Professor Heymans of Ghent, who had been punished severely by the Nazis for publishing it. The daily basic ration was only 1,230 calories. Certain classes were allowed supplementary rations, but although rations were adequate for the younger children they were worse as age advanced. A loss of 10 to 15 Kg. in weight was common. Tuberculosis was rife and was increasing.

Treatment of Cancer of the Prostate by Synthetic Estrogens

At a meeting of the British Empire Cancer Campaign, Prof. E. C. Dodds, Courtauld professor of biochemistry in the University of London and director of the Courtauld Institute of Biochemistry, Middlesex Hospital, called attention to results obtained in treating cancer of the prostate with synthetic estrogens. As a nation, Professor Dodds stated, we could take a certain amount of credit in the discovery of this method, for, while the actual observations of cases were made by our American colleagues, the weapon which they used was forged by Englishmen working directly under the support of the British Empire Cancer Campaign. Statistics for 1941 showed that this discovery would eliminate intense suffering and death of about 4,000 persons annually in England and Wales, he said; for the first time in history it was possible to state that one form of cancer could be completely controlled and the patient rendered symptom free by giving a few pills each day. The American work had been completely confirmed here, Professor Dodds said. He warned that the discovery was confined to cancer of the prostate. Whether or not it uncovered an entirely new field of research had still to be determined, he felt, and would be investigated by those working with the support of the campaign.

The speaker indicated that it was impossible even for the average scientific worker to realize the tremendous increase in knowledge that had taken place not only during the twenty years existence of the campaign but even since the beginning of the war. The laboratory of ten years ago was almost as much out of date today as one 50 years old. The whole technic of pathology and biochemical research had been utterly changed by the introduction of new methods, Professor Dodds stated, and the technical use of the new instruments required new and deep knowledge of a most complex character.

The duke of Gloucester, brother of the king, who presided, said that the campaign would soon reach its twenty-first anniversary. During the years that he had been their president, he said, he had seen much to convince him that all associated with the campaign would some day gain their reward in the knowledge that they had contributed much toward victory in the war against cancer. He emphasized that cancer research was slow and laborious work, with little if any glamor or lime-light, but that many more young enthusiastic workers would be attracted to it were they not anxious about their daily existence. Apart from financial support of the personnel at large research centers, the campaign had always tried to encourage these young enthusiasts, and he was glad to know that generous contributors from time to time made provision for the creation of cancer research scholarships and fellowships.

Prevention of Tuberculosis in Nursing Staffs of General Hospitals

In a memorandum on the supervision of nurses' health a committee of three nursing matrons under the chairmanship of Sir Charlton Briscoe has made important suggestions on the prevention of tuberculosis among nursing staffs of general hospitals. It is pointed out that the nurse in a general hospital is not so well safeguarded against infection with tuberculosis as the nurse in a sanatorium, in which there is equipment for sterilizing sputum mugs, china and handkerchiefs, and where the nurse does much of her work in the open air. In general hospitals the new and untrained student nurse often has to handle sputum mugs, and handkerchiefs are often allowed to accumulate in a patient's locker until his relatives call for them. A sink may become contaminated if china from infectious patients is washed there.

Among the other recommendations made by the committee are the following: All nurses should be taught throughout their training by sister tutors and war sisters the precautions necessary in the nursing of the tuberculous and shown how infection is spread in respiratory conditions. They should learn how the patient can avoid distributing droplet infection, that the hands of those nursing patients with positive infection should be washed often and that no books or papers belonging to such patients should be lent to others. They should remove the overall or apron worn in the ward before going to meals. They should be encouraged to report at once any cough or respiratory infection which they notice in themselves, and especially any persistent feeling of fatigue. All nurses under 30 who are nursing tuberculous patients should be examined by x-rays at three month intervals. Every patient who is coughing up sputum should be nursed "on precautions," if possible in a separate ward, until tuberculosis is excluded. Whenever possible a boiler should be installed so that all sputum mugs can be sterilized before cleaning. The hospital should provide the patient with handkerchiefs and have special arrangements for laundering them. Bed linen should be collected and sterilized with proper precautions. Methods of sweeping and dusting around beds should be such as to avoid dissemination of infected dust. If there is no sterilizer for china, that used by tuberculous patients should be washed in a separate sink.

The Influenza Epidemic

The outbreak of an epidemic of influenza all over the country was reported in a previous letter. The epidemic began in the North, where already it shows signs of abating, although the peak does not appear to have been reached in London and the Midlands. Its development is shown by the deaths attributed to influenza in the large cities. For the weeks from November 13 to December 11 the deaths reported were respectively 46, 106, 375, 709 and 1,148. These deaths occurred mainly among the elderly. As a result the attacks have been mild with pyrexia of only three or four days and no complications. The most common complication is tracheobronchitis and, in the severe cases, bronchiolitis with patches of bronchopneumonia. This type has been responsible for deaths in young as well as old persons. The epidemic has slightly impaired the war effort. The shortage of doctors has left too few for this emergency. The government is giving help by allowing the army doctors to assist in the treatment of civilian patients as far as their military duties permit. There is also a shortage of pharmacists and dispensers, and therefore the call of these workers for war service has been temporarily suspended.

Standardization of the Test for Latent Tuberculin Allergy in Man

Dr. Arlindo de Assis of the Viscondessa de Morais Tuberculosis Institute of Rio de Janeiro has been carrying on extensive studies of the pathogenicity of the BCG bacillus and intratuberculin allergy and has been able to establish a standard technic for the so-called Willis test. As a conclusion to his first series of studies Dr. de Assis was able to prove that during the course of the primary tuberculous infection of infancy the tuberculin allergy of the skin is established through a pre-allergic period the presence of which had not been demonstrated before. This led him to a second conclusion: that the intradermal inoculation of 0.1 mg. of heat killed BCG vaccine in children who are in the preallergic period is accompanied by specific and characteristic reactions permitting recognition of the preexistence of a virulent tuberculous infection before the appearance of cutaneous allergy and consequently of x-ray signs and clinical symptoms. Dr. de Assis's latest series of investigations has been aimed at study of the period of allergy that frequently follows the BCG vaccination at a short interval if the immunized person has the chance to escape entirely the added action of other virulent bacilli.

Forty-two children immunized by mouth with BCG were tested intradermically with old tuberculin and recognized as having lost the allergy specifically caused by vaccination after variable lengths of time. Only those children who failed to react to Mantoux tests with 10 mg. of old tuberculin were included in the study. They all have been kept under complete medical care for a long time and are recognized as free from tuberculous disease. Heat killed tubercle bacilli were injected intradermically, 0.1 mg. having been chosen as the test dose. According to previous observations an early appearance of tuberculin hypersensitiveness was checked after a fourteen day period as a routine method of detecting latent or intratuberculin allergy. Clearcut infiltrations reaching 6 mm. in diameter at the site of the inoculation were considered reliable proof of a preexisting latent allergy, as were positive tuberculin tests occurring at the beginning of the first week after the inoculation of heat killed bacilli. On the basis of such criteria, 32 children (76.2 per cent) proved to keep latent BCG allergy, although some of them had failed to react to routine tuberculin tests for seven years previously. All the children presented local infiltrative changes. General tuberculin responses were found less frequently than local ones, 16 children (50 per cent

of the positive cases) having shown positive tuberculin tests within the first week following the heat killed bacillus test. No definite relationship could be established between local changes promoted by the heat killed bacillus injection and the early causes of tuberculin hypersensitiveness. Oral revaccinations with living BCG did not exert any apparent influence on the frequency or intensity of the latent allergy. Since this kind of allergy has been frequently found in children who resisted virulent tuberculosis environments, the conclusion was drawn that the refractory status against tuberculous disease does not necessarily imply an ability to react to current tests for tuberculin hypersensitiveness. In these children the immunity to tuberculosis was rather associated with the latent allergy.

Two New Cases of Human Toxoplasmosis

Dr. Nery Guimarães of the Oswaldo Cruz Institute published recently a paper describing an established case and a suspected case of human toxoplasmosis occurring in rural sections of Brazil. With the initial work of Castellani in 1914, investigators of various countries have reported the occurrence of human toxoplasmosis, a fact that not long ago was a matter of sharp controversy. About 18 established cases were reported between 1923 and 1942 in Praga, in New York, in St. Louis, in Chicago, in Cincinnati, in Rio de Janeiro and in Amsterdam by Janku, Wolf and Cowen, Page, Sabin, Pinkerton, Torres, Wolf and De Lange, of which 10 were congenital. The symptoms presented by the patients were principally fever, convulsions, hydrocephalus, cyanosis and vomiting. Although no detailed microscopic studies have been done in all cases, the disease is characterized by granulomatous meningoencephalomyelitis (Wolf and Cowen), often associated with myocarditis and chorioretinitis. But the diagnostic sign of greatest importance is the presence of foci of profound cerebral calcification and chorioretinitis in the newborn (Wolf, Cowen and Page). Generally the disease has been encountered in towns on post-mortem examination, with subsequent hospital observations. Yet in some cases a more or less long stay in suburban and rural sections was pointed out. This fact seems to be of great epidemiologic importance. The parasite is found in a large number of animals in more or less intimate contact with man, but how the disease is transmitted to man is not established, nor is the transmission of toxoplasmas among animals known as yet. Dr. Guimarães's patient was a Negro youth of 18, an agricultural laborer, whose disease lasted twenty-seven days and was characterized by high fever, paresis of the lower limbs, nuchal rigidity, dysphasia and monocytosis. The postmortem macroscopic and microscopic examinations showed encephalitis, pericarditis, nephritis and a meningoencephalomyelitis with extensive inflammatory areas. The presence of the parasites was established. The second patient was a mulatto girl baby aged 14 months, born with hydrocephalus and presenting agitation, convulsions and tremor of the eyeballs. The x-ray examination showed typical little foci of cerebral calcification and deficient ossification of the extremities of the long bones. Toxoplasmas were isolated from guinea pigs and mice inoculated with fluid from the patient. The isolated strain appeared to be pathogenic for dogs, guinea pigs, rabbits, mice and pigeons.

Marriages

RANDOLPH CASSELLS CHARLES to Miss Harriet Winston Breeden, both of Bennettsville, S. C., November 25.

JOHN MARCUS KESTER JR. to Miss Lura Kirkland, both of Columbia, S. C., at Sumter, November 5.

E. THOMAS BRAND, Woodstock, Ill., to Mrs. Martha H. Brigham of Seneca, November 26.

DOUGLAS H. ROBERTSON to DR. RUTH F. GEISSINGER, both of New York, December 18.

Deaths

Charles Henry May ☉ New York; College of Physicians and Surgeons, New York, 1883; member of the American Academy of Ophthalmology and Otolaryngology, American Ophthalmological Society and the Association for Research in Ophthalmology, Inc.; fellow of the American College of Surgeons; specialist certified by the American Board of Ophthalmology; lecturer in diseases of the eye, New York Polyclinic, from 1887 to 1890; instructor in ophthalmology and chief of clinic at his alma mater from 1890 to 1903; served on the staffs of the Monmouth Memorial Hospital, Long Branch, N. J., French Hospital and the Mount Sinai Hospital; director and visiting surgeon, eye department, Bellevue Hospital, from 1915 to 1925 and later consulting ophthalmic surgeon; in 1914 introduced the improved system of illumination for electric ophthalmoscopes; author of "Manual of Diseases of the Eye"; recently completed revision of the eighteenth edition; the book had been translated into ten foreign languages; died December 7, aged 82, of pneumonia.

Frederick Casper Rinker ☉ Norfolk, Va.; University of Virginia Department of Medicine, Charlottesville, 1911; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; president-elect of the Norfolk County Medical Society; member and past president of the Southside Virginia Medical Society; formerly assistant professor of clinical medicine at the University of Wisconsin Medical School, Madison; a lieutenant in the U. S. Army during World War I; a member of the U. S. Naval Reserve; examining physician for the local board of the Selective Service System; on the staffs of the Norfolk General Hospital, Hospital of St. Vincent De Paul and the Leigh Memorial Hospital, where he died November 15, aged 58, of sclerotic heart disease.

David M. R. Culbreth, Baltimore; College of Physicians and Surgeons, Baltimore, 1883; for many years professor of botany, materia medica and pharmacognosy, Maryland College of Pharmacy, and professor of materia medica and pharmacognosy in the medical and dental departments of the University of Maryland; honorary president of the American Pharmaceutical Association, 1935-1936; member of the American Academy of Medicine and the Maryland Academy of Science; author of "Pharmaceutical Botany," "Materia Medica and Pharmacology," "Materia Medica Compend" and "University of Virginia—Memories of Her Student Life and Professors"; died October 20, aged 87.

Albert Warren Wagner, Buffalo; University of Buffalo School of Medicine, 1910; member of the Medical Society of the State of New York; also a pharmacist; served in the medical corps of the U. S. Army during World War I; medical examiner for the Cheektowaga Selective Service during World War I and recently; health officer of Cheektowaga and medical examiner for public and parochial schools for many years; on the staff of the Deaconess Hospital; died in the Veterans Administration Facility, Batavia, N. Y., November 15, aged 61, of hypertensive and coronary arterio-sclerotic heart disease.

Raymond Duane Sleight, Battle Creek, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897; specialist certified by the American Board of Ophthalmology; member of the Michigan State Medical Society, American Academy of Ophthalmology and Otolaryngology and the Association for Research in Ophthalmology, Inc.; served in France and in the medical corps of the U. S. Army during World War I; recently examiner for the local draft board; on the staffs of the Community and the Leila Y. Post Montgomery hospitals; died December 7, aged 68, of cerebral hemorrhage.

Frank Warner ☉ Columbus, Ohio; Bellevue Hospital Medical College, New York, 1883; member of the House of Delegates of the American Medical Association in 1902 and 1903; fellow of the American College of Surgeons; at one time professor of operative and clinical surgery at the Starling Medical College; for many years a member of the state board of health; on the surgical staffs of the Grant, White Cross and Children's hospitals; trustee of the Columbus Public Library since 1910; died in the University Hospital November 28, aged 88, of heart disease.

Josiah Odin Tilton, Lexington, Mass.; University of the City of New York Medical Department, New York, 1882; member of the Massachusetts Medical Society; the first school physician in Lexington; served on the local board of health and as chairman of the Lexington park commissioners; in

1932 a bronze tablet in his honor was placed in the New England Medical Center in Boston in recognition of a "lifetime of unselfish service to the community of Lexington"; died in the Metropolitan Hospital, Waltham, December 2, aged 90, of pneumonia.

Michael Abramowicz, New York; Medizinische Fakultät der Universität, Wien, Austria, 1920; was killed December 1, aged 51, when a self-service elevator from which he was alighting suddenly started upward and crushed him.

Joseph Akerman ☉ Augusta, Ga.; Johns Hopkins University School of Medicine, Baltimore, 1900; professor of obstetrics at the University of Georgia School of Medicine; member of the South Atlantic Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; superintendent of the James Walker Memorial Hospital, Wilmington, N. C., from 1902 to 1906; from 1916 to 1917 superintendent of the University Hospital, where he had been a member of the staff; died December 9, aged 71, of heart disease.

Samuel Lane Anderson, Concordville, Pa.; Medico-Chirurgical College of Philadelphia, 1892; died November 10, aged 79.

William Clifford Bailey ☉ Decatur, Ala.; Medical College of Alabama, Mobile, 1906; on the staff of the Benevolent Society Hospital; local surgeon for the Southern Railroad; surgeon for the Southern Oil and Alabama Power Company; died recently, aged 61, of thrombosis.

William Dwight Baldwin, Makawao Maui, Territory of Hawaii; Johns Hopkins University School of Medicine, Baltimore, 1901; member of the Hawaii Territorial Medical Association; died October 31, aged 70, of coronary thrombosis.

Ira Bennett Bartle, San Luis Obispo, Calif.; Medical Department of Tulane University of Louisiana, New Orleans, 1901; member of the California Medical Association; served during World War I; president of the San Luis Obispo Rotary Club; died November 7, aged 72.

Arthur Joseph Batty ☉ Portage, Wis.; Rush Medical College, Chicago, 1906; fellow of the American College of Surgeons; veteran of the Spanish-American War and World War I; president of the First National Bank; for many years president of the chamber of commerce; on the staff of St. Savior's Hospital, where he died December 4, aged 62, of gastric hemorrhage due to ulcer.

James Bedsole, Hacoda, Ala.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1906; member of the Medical Association of the State of Alabama; died November 2, aged 72.

Edmond E. Blaauw ☉ Buffalo; Universiteit van Amsterdam Geneeskunde Faculteit, Netherlands, 1893; member of the American Academy of Ophthalmology and Otolaryngology; died December 4, aged 76, of coronary disease.

Charles H. Brobst, Peoria, Ill.; Medico-Chirurgical College of Philadelphia, 1888; member of the Illinois State Medical Society and the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; for many years on the staff of the Proctor Hospital, where he died November 25, aged 79.

Edward Morton Buck, Montrose, Iowa; Keokuk Medical College, 1896; chairman of the board of health, school examiner and president of the school board; on the staff of St. Joseph Hospital, Keokuk, where he died November 30, aged 78, of cardiac asthma.

Allen W. Budd, Canton, Ohio; Cleveland Medical College, 1880; died December 10, aged 91, of senility.

William Sabin Chase, Akron, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901; past president of the Summit County Medical Society; served on the staff of the City Hospital; a founder and on the staffs of the Peoples and Children's hospitals; died December 1, aged 76, of a self-inflicted bullet wound.

George Henry Cleveland, Glencoe, Ill.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1882; at one time editor of the *Clinical Review*; died in the Broadhurst Nursing Home, Evanston, December 19, aged 81, of chronic myocarditis and arteriosclerosis.

Elmer Lorenzo Crouch, Palo Alto, Calif.; Missouri Medical College, St. Louis, 1891; member of the American Psychiatric Association; served during World War I; at one time assistant physician on the staff of the Jacksonville (Ill.) State Hospital; for many years on the staff of the Veterans Administration Facility, San Francisco; died in the Palo Alto Hospital November 25, aged 74, of carcinoma.

James Francis Curry, Dunnellon, Fla.; Emory University School of Medicine, Atlanta, 1919; died in the Munroe Memo-

rial Hospital, Ocala, November 3, aged 48, of injuries received in an automobile accident.

Pierce Young Duckett, Cornelia, Ga.; University of Georgia Medical Department, Augusta, 1885; member of the Medical Association of Georgia; died in Decatur November 18, aged 81, of pneumonia.

Hiram R. Elliott Sr., Courtland, Miss.; Memphis (Tenn.) Hospital Medical College, 1900; died November 27, aged 69, of tumor of the brain.

Charles Chauncy Foster, Cambridge, Mass.; Harvard Medical School, Boston, 1883; member of the Massachusetts Medical Society; veteran of the Spanish-American War; formerly surgeon general of the commonwealth with the rank of brigadier general; served on the staff of the Cambridge Hospital; died December 2, aged 86, of diabetes mellitus.

Jacob Adam Fraunfelder * Nazareth, Pa.; Medico-Chirurgical College of Philadelphia, 1896; also a pharmacist; past president of the Northampton County Medical Society; medical examiner for the borough of Nazareth recently and during World War I; for many years physician for the borough schools; past president of the Rotary Club; died November 6, aged 71.

Fredrick George Gilbert, Rapid City, S. D.; Homeopathic Hospital College, Cleveland, 1889; died in St. John's McNamara Hospital November 14, aged 76.

Leonard Harry Green, Los Angeles; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1922; member of the California Medical Association; specialist certified by the American Board of Pediatrics, Inc.; on the staffs of the Cedars of Lebanon Hospital and the Children's Hospital; died recently, aged 46.

James Taylor Hammond, Atlanta, Ga.; University of Georgia Medical Department, Augusta, 1883; member of the Medical Association of Georgia; died in Albany November 2, aged 87.

Samuel Smith Hill * Wernersville, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1894; member of the American Psychiatric Association; formerly superintendent of the Wernersville State Hospital; for many years president of the Wernersville National Bank; died in the Reading Hospital, Reading, November 22, aged 75, of carcinoma of the stomach.

John Sutherland Hurt, Atlanta, Ga.; University and Bellevue Hospital Medical College, New York, 1903; member of the Medical Association of Georgia; died November 26, aged 66.

Wilbur Olin Jenkins * Indianapolis; Medical College of Ohio, Cincinnati, 1884; served as secretary of the city board of health and as a member of the board of public works, and safety; at one time on the staff of St. Anthony's Hospital, Terre Haute; died December 3, aged 82.

Victor Monroe Johnson, Memphis, Tenn.; Bellevue Hospital Medical College, New York, 1888; Arkansas Industrial University Medical Department, Little Rock, 1896; died December 12, aged 80, of secondary anemia.

Ellis Kackley, Soda Springs, Idaho; University of Tennessee Medical Department, Nashville, 1898; served during World War I; medical superintendent of the Caribou County Hospital; died November 22, aged 72.

William E. Lawson, Homestead, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1897; formerly member of the school board; on the staff of the Homestead Hospital; died November 26, aged 71, of coronary occlusion.

Wesley P. Lewallen, Canadian, Okla.; Kentucky School of Medicine, Louisville, 1901; died October 18, aged 81.

Elverton E. Major, Los Angeles; Rush Medical College, Chicago, 1878; died November 12, aged 89.

James Ragan McEachern * Tampa, Fla.; Atlanta College of Physicians and Surgeons, 1902; served as president of the Florida Public Health Association; at one time a member of the city council of Monticello, a member of the state senate and legislature; served in the medical corps of the U. S. Army in France during World War I; health officer of Tampa; died suddenly in November, aged 70.

John Seaborn McKenzie, Miami, Fla.; Louisville (Ky.) Medical College, 1892; died in a local hospital October 17, aged 77.

John J. McShane, Springfield, Ill.; Rush Medical College, Chicago, 1903; member of the Illinois State Medical Society; chief of the division of communicable diseases, state department of public health; at one time a member of the health department

of Chicago and health commissioner of Kenosha, Wis.; died in St. John's Hospital December 14, aged 65, of cerebral hemorrhage.

B. B. Meroney, Murphy, N. C.; Gate City Medical College, Texarkana, Ark., 1906; died in a local hospital November 19, aged 77.

John Sewall Milliken * Portland, Maine; Medical School of Maine, Portland, 1900; served during World War I; died in the Maine General Hospital recently, aged 67, of chronic rheumatic heart disease.

Henry Pinckney Moore, Orangeburg, S. C.; Medical College of the State of South Carolina, Charleston, 1912; served during World War I; on the staff of the Tri-County Hospital; died December 9, aged 56, of coronary thrombosis.

Donn Piatt Murray * Dunkirk, Ind.; Medical College of Indiana, Indianapolis, 1894; a director and vice president of the First State Bank of Dunkirk; for many years president of the school board; on the staffs of the Jay County Hospital, Portland, and the Ball Memorial Hospital, Muncie, where he died November 9, aged 73.

Stephen Dixon Naylor, Stephenville, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1890; member, and vice president 1928-1929, State Medical Association of Texas; served as medical examiner of cadets at John Tarleton College; for many years a member of the board of directors of the chamber of commerce; died in a local hospital October 17, aged 77, of cerebral hemorrhage.

Lera Page, Rutherford, Tenn. (licensed in Tennessee in 1913); served as postmaster; died November 25, aged 68.

Harry Middleton Parker, Wedgefield, S. C.; Medical College of the State of South Carolina, Charleston, 1913; member of the South Carolina Medical Association; served during World War I; died November 29, aged 59.

Jefferson Thompson Parks Jr., Oklahoma City; University of Oklahoma School of Medicine, Oklahoma City, 1943; died in the Wesley Hospital November 11, aged 34, of pulmonary tuberculosis.

Roger V. Parlett, Tucson, Ariz.; University of Maryland School of Medicine, Baltimore, 1912; served overseas during World War I; served as physician and surgeon for the Sundt Construction Company; at one time associated with the Indian Service and U. S. Public Health Service; died in St. Mary's Hospital November 6, aged 55, of uremia.

James Denham Pasco, Jacksonville, Fla.; University of Virginia Department of Medicine, Charlottesville, 1906; member of the Florida Medical Association; on the staffs of the Riverside Hospital and the Church Home for Boys; died November 12, aged 60, of perforating ulcer of stomach.

Harold Foster Port * Titusville, Pa.; University of Pittsburgh School of Medicine, 1928; served overseas during World War I; a member of the local board of health; on the staff of the Titusville Hospital; died November 13, aged 49.

Joseph Charles Pothier * New Bedford, Mass.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1887; formerly a member of the school committee; on the courtesy staff, St. Luke's Hospital; died December 1, aged 78, of coronary infarct.

Elmer John Presper, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1912; member of the Medical Society of the State of Pennsylvania; served overseas during World War I; medical examiner for the civil service commission for many years; on the staffs of St. Mary's and St. Christopher's hospitals; died in the U. S. Naval Hospital December 2, aged 52, of cirrhosis of the liver.

Coleman Bernard Ransone * Roanoke, Va.; Medical College of Virginia, Richmond, 1915; health commissioner of Roanoke; at one time health officer of Newport News; served in the U. S. Navy from 1917 to 1920; died December 3, aged 56, of coronary thrombosis.

Arthur Earnest Rogers, Jacksonville, Fla.; Rush Medical College, Chicago, 1897; served during World War I; died in the Veterans Administration Facility, Bay Pines, November 15, aged 73, of acute bronchopneumonia.

Clarence Otis Sansing * Houston, Texas; Baylor University College of Medicine, Dallas, 1926; for many years lieutenant in the medical reserve corps of the U. S. Army; served on the staffs of the Hermann Hospital, St. Joseph's Infirmary, Memorial Hospital, Jefferson Davis Hospital and the Methodist Hospital; died November 17, aged 45, of coronary occlusion.

William Frederick Schenk, New Corydon, Ind.; Curtis Physio-Medical Institute, Marion, 1896; served as a member

of the local board of health; for many years member of the state legislature; director of the Bank of Geneva; died in the Adams County Memorial Hospital, Decatur, November 28, aged 77, of hemorrhage due to ruptured aneurysm.

Minnie Myrtle Seiler, Fort Myers, Fla.; Woman's Medical College of Baltimore, 1904; died November 14, aged 65.

Daniel Anderson Simmons * Roseville, Ill.; University of Illinois College of Medicine, Chicago, 1929; local health officer; on the staff of the Monmouth Hospital, Monmouth; died in the University Hospital, Chicago, November 18, aged 39, of respiratory failure following a nephrectomy.

George Wallace Simrell, Brooklyn; Long Island College Hospital, Brooklyn, 1899; also a pharmacist; member of the Medical Society of the State of New York; served in the medical corps of the U. S. Army during World War I; formerly on the staffs of the Swedish, Caledonian and Midwood hospitals; died in the Veterans Administration Facility, Northport, N. Y., November 30, aged 74, of chronic myocarditis.

Edward A. Smith * Baltimore; Baltimore Medical College, 1891; died November 1, aged 81, of chronic myocarditis.

William A. Smith, Madison, Va.; University of Maryland School of Medicine, Baltimore, 1880; member of the Medical Society of Virginia; died November 10, aged 88, of senility.

William Edgar Sperow, Carlisle, Iowa; University of Maryland School of Medicine, Baltimore, 1894; member of the Iowa State Medical Society; on the staff of the Iowa Lutheran Hospital, Des Moines; died in the Iowa Methodist Hospital, Des Moines, November 10, aged 72, of heart disease.

Charles Abraham Spivacke * New York; Cornell University Medical College, New York, 1899; member of the American Association for the Study of Allergy; a founder and director of the allergy clinic, Lebanon Hospital dispensary; died November 21, aged 66.

Walter Thomas Stenson * New York; McGill University Faculty of Medicine, Montreal, Que., Canada, 1922; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; served during World War I; on the surgical staff of the Lenox Hill Hospital; died in Punta Gorda, Fla., December 8, aged 48, of acute pulmonary congestion and coronary thrombosis.

Daniel Boone Stone, Smiths Grove, Ky.; University of Tennessee Medical Department, Nashville, 1888; member of the Kentucky State Medical Association; died November 6, aged 83.

Arthur MacMahan Sullivan, South Bend, Ind.; Indiana University School of Medicine, Indianapolis, 1909; member of the Indiana State Medical Association; died November 27, aged 62.

Louie P. Tessier, Augusta, Ga.; University of Georgia Medical Department, Augusta, 1896; served as city physician; formerly a druggist; died November 27, aged 71.

Constantine Theodore, Chicago; National University of Athens School of Medicine, Greece, 1902; member of the American Association of Railway Surgeons; a member of the Selective Service Board number 3; on the staff of the Illinois Central Hospital; founder and organizer of the Greek Grammar School at St. Constantine Church; for twenty-eight years Cook County jail physician; past president of the Greek Professional Mens Club; died November 24, aged 64, of chronic myocarditis and chronic bronchiectasis.

Clive Wylie Thompson, Cleveland; University of Wooster Medical Department, Cleveland, 1907; member of the Ohio State Medical Association; veteran of the Spanish-American War and World War I; served on the staffs of the Huron Road Hospital, East Cleveland, and St. Luke's Hospital; died November 7, aged 64, of coronary occlusion.

David Orval Thompson, Sycamore, Ill.; Chicago Medical School, 1923; member of the Illinois State Medical Society; a director of the Illinois Tuberculosis Association and the De Kalb County Tuberculosis Association; on the staffs of the De Kalb Public and St. Mary's hospitals, De Kalb, and the Sycamore Municipal Hospital; a member of the chamber of commerce; died November 6, aged 60, of coronary thrombosis.

Charles Ethelbert Triplett, Morocco, Ind.; Rush Medical College, Chicago, 1895; died November 25, aged 81, of carcinoma of the prostate and bladder.

Charles Sutton Trites, Napanoch, N. Y.; Hahnemann Medical College and Hospital of Philadelphia, 1896; member of the American Psychiatric Association; on the staff of the Institution for Male Defective Delinquents; at one time staff psychiatrist, Auburn Prison, Auburn; died in the Veterans Memorial Hospital, Ellenville, December 7, aged 68, of pneumonia.

Herman H. Tuttle, Springfield, Ill.; Keokuk (Iowa) Medical College, 1894; cited for gallantry in action in World War I; at one time health officer of Springfield; died in the Veterans Administration Facility, Downey, December 9, aged 72, of chronic myocarditis with myocardial degeneration and general arteriosclerosis.

William Alva Van Wart, Cherryfield, Maine; Bellevue Hospital Medical College, New York, 1893; died November 2, aged 75.

Benjamin S. Walker, Corydon, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1900; member of the Iowa State Medical Society; served during World War I; a member of the town council, school board and Rotary Club; on the staff of the Corydon Hospital; died November 2, aged 70, of hypertension and cerebral hemorrhage.

Horace Seeley Warner, Thomaston, Conn.; College of Physicians and Surgeons, New York, 1884; member of the Medical Society of the State of New York; for many years medical referee of the Aetna Life Insurance Company, New York; died November 30, aged 85, of myocarditis.

Richard Cornell Warren * Ithaca, N. Y.; Cleveland Homeopathic Medical College, 1903; veteran of the Spanish-American War; on the staff of Tompkins County Memorial Hospital; died December 15, aged 69, of coronary thrombosis.

Albert G. Wilkinson, Wayne, W. Va.; Louisville (Ky.) Medical College, 1893; president of the Wayne County Bank; county health officer; died November 29, aged 77, of heart disease.

Albert Ross Wilsey, Breckenridge, Mo.; St. Louis University School of Medicine, 1902; served during World War I; died in the Missouri Methodist Hospital, St. Joseph, November 7, aged 70, of strangulated hernia and intestinal obstruction.

Peter Joseph Wollersheim, Forest Junction, Wis.; Marquette University School of Medicine, Milwaukee, 1928; member of the State Medical Society of Wisconsin; on the staffs of St. Vincent's and Bellin Memorial hospitals, Green Bay; died in Stevens Point November 28, aged 48, of pneumonia.

John Henry Young * Lemongrove, Calif.; Ohio Medical University, Columbus, 1900; fellow of the American College of Surgeons; attending obstetrician and gynecologist, San Diego County and Mercy hospitals, San Diego, and Scripps Memorial Hospital, La Jolla; died October 14, aged 70, of a self-inflicted bullet wound.

Edward Anthony Zaworski * Minneapolis; John A. Creighton Medical College, Omaha, 1911; served as vice president of the Northeast State Bank; medical examiner for the northeast section draft board; died November 25, aged 58, of coronary heart disease and hypertension.

KILLED IN ACTION

Charles Frederick Pecoraro, Somerville, Mass.; College of Physicians and Surgeons, Boston, 1937; captain, medical corps, Army of the United States and was assigned to the medical detachment, 532d Engineer Regiment; died in the southwest Pacific area September 25, aged 35, of wounds received in action.

CAPT. CHARLES F. PECORARO
M. C., A. U. S., 1908-1943

DEVICE TO AID WASHING OF HAND BY PATIENT WITH AMPUTATED ARM

To the Editor.—Recently, without thinking, I told a one armed man who was in my office to wash his hand. He replied "How would I do it?" Obviously his plight is similar to the plight of many others and there probably will be many more when the casualties of the war come back. I am sending you a brush which I have prepared for the use of this patient. I have never seen or heard of any similar device nor have my friends who have seen it.

I would appreciate your publishing a picture of this simple, inexpensive and, above all, very efficient device, which the patient can carry with him and use at any time or place. The little rubber vacuum cups are still available in Indianapolis in

Brush fitted with vacuum cups.

limited quantities and if the brush would meet any great demand it probably could be manufactured economically by a large manufacturer of brushes.

The idea is simply to attach two rubber vacuum cups to any brush. As far as I know, this particular use of the vacuum cup is new and I hope the idea will be of value to the unfortunate cripples who need it.

JOHN R. BRAYTON, M.D., Indianapolis.

LEPROSY

To the Editor.—Careful reading of a recent article by Frazier (Leprosy, Epidemiology and Natural History, *THE JOURNAL*, Oct. 23, 1943, p. 466) leaves me a bit bewildered. Why was it written? For the worker in leprosy who is familiar with the literature it contains nothing new, although some points are controversial, such as his statements regarding transmission. If it is for the general practitioner or dermatologist who may see an occasional case of leprosy, it is dangerous. Here are my reasons:

The section on natural history is true for the most part but ignores the accepted classification which is the basis for diagnosis, study and prognosis (The Cairo Congress, Report of the Subcommittee on Classification, *Internat. J. Lep.* 6:389 [July-Sept.] 1938). One might think from Frazier's discussion that lesions may shift from tuberculoid to lepromatous and back to simple neural. This simply does not happen or, if it does, it is so rare that it has not to my knowledge been reported.

Regarding examination for *Mycobacterium leprae*, he states "Fixed tissue preparations of skin and lymph node are best for this purpose." Fixed skin preparations are of value only when bacilli are extremely scanty. Lymph node preparations are of much less value because of the difficulty in identifying bacilli found there as *M. leprae*. But in all lepromatous cases, and probably in the majority of cases in which bacilli will be demonstrated, Wade's "scraped incision" method is quite satisfactory (Wade, H. W.: *The Bacteriological Examination in Leprosy*, *Lep. Rev.* 6:54, 1925). Moreover, in simple leprids one does not expect to find bacilli except, perhaps, in the nerves.

Today millions of young Americans are going into regions where leprosy is endemic, and the experience of the Philippine campaigns of the Spanish-American War is likely to be repeated on a larger scale. All the members of our armed forces should realize that leprosy, which may be unrecognized but contagious, is abundantly present in Polynesia, China, the Philippines, the East Indies, Thailand, Burma, India, Arabia, central and northern Africa, and even to some extent in southern Europe. Medical officers should be familiar with early symptoms of the disease in order to protect their troops as much as possible; but the general practitioner who five or ten years from now will see the returned soldier who begins to show signs of leprosy should also be able to recognize and diagnose the condition. Teach the medical profession to suspect and to diagnose leprosy; further study and treatment, if any, may well be left to special workers in that field.

NORMAN R. SLOAN, M.D., Kalaupapa, Molokai, T. H.
Medical Director.

POSTURE DURING EXAMINATION OF HEART

To the Editor.—In the Nov. 13, 1943 issue of *THE JOURNAL* a clinical note appeared with reference to posture during examination of rapid heart by Dr. L. S. Luton of St. Louis. The author states that it was "something new to him" when he noticed that a tachycardia in a patient he had been examining had abruptly terminated on the patient bending forward.

In a paper on "Paroxysmal Auricular Flutter of 1:1 Ratio," page 955 of Vol. 8 of the *Annals of Int. Med.* 1935, I quoted a communication from the patient under study for this condition in which he stated that he was able "to ward off an attack of the extremely rapid type by bending forward when the heart seemed undecided whether to go back on its regular beating or to take up the very fast palpitating route." This patient used to have attacks of tachycardia of 240 rate which was considered to be auricular flutter of 1:1 ratio.

On many occasions I have observed that patients subject to such paroxysms knew how to terminate such attacks by "doubling up on themselves" or "squatting down."

U. S. Marine Hospital,
New York.

HYPOGLYCEMIC ACTION OF NICOTINIC ACID

To the Editor:—THE JOURNAL, Nov. 27, 1943 contains an abstract of an article by F. J. Neuwahl on the hypoglycemic action of nicotinic acid (*Lancet* 2:348 [Sept. 18] 1943). The following quotation is taken from an abstract of my report made at the meeting of the American Physiological Society in the spring of 1935 at Detroit and published in September of the same year in the proceedings: "Nicotinic acid exerted a mild hypoglycemic action. . . . In all cases an increase of muscular sensitivity, decrease of body temperature and slowing of heart beat were noted. The hypoglycemic action of nicotinic acid was most pronounced in turtles."

NATIONAL BOARD OF MEDICAL EXAMINERS
EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, Jan. 15, page 188.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, Feb. 21-24. Sec., Dr. B. F. Austin, 519 Dexter Ave., Montgomery.

ARKANSAS: * March. Sec., Dr. D. L. Owens, Harrison.

COLORADO: * Denver, April 4-7. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.

CONNECTICUT: * Medical, Written, Hartford, March 14-15. Endorsement, New Haven, March 28. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven. Homoeopathic, Derby, March 13-14. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

FLORIDA: * Jacksonville, June 26-27. Sec., Dr. W. M. Rowlett, Box 786, Tampa.

INDIANA: Indianapolis, May 2-4. Sec., Board of Medical Registration and Examination, Dr. W. C. Moore, 301 State House, Indianapolis.

KANSAS: Kansas City, Feb. 2-3. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.

MAINE: Portland, March 14-15. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

MASSACHUSETTS: Boston, March 14-17. Sec., Board of Registration in Medicine, Dr. H. Q. Galluppe, 413-F State House, Boston.

MISSOURI: Reciprocity, Jefferson City, Jan. 24. Sec., State Board of Health, Dr. James Stewart, State Capitol Bldg., Jefferson City.

MONTANA: Helena, April 3-5. Sec., Dr. O. G. Klein, First National Bank Bldg., Helena.

NEVADA: Endorsement, Carson City, Feb. 7. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: Concord, March 9-10. Sec., Board of Registration in Medicine, Dr. D. G. Smith, State House, Concord.

NEW JERSEY: Feb. 15-16. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: * Santa Fe, April 10-11. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

NEW YORK: Albany, New York, Buffalo and Syracuse, Jan. 24-27. Sec., Dr. R. R. Hannon, Education Bldg., Albany.

OHIO: Endorsement, Columbus, Feb. 7. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OREGON: * Portland, Jan. 26-29. Exec. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland.

RHODE ISLAND: * Providence, April 6-7. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

WYOMING: Cheyenne, Feb. 7-8. Sec., Dr. M. C. Keith, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

COLORADO: Denver, March 8-9. Sec., Dr. E. B. Starks, 1459 Ogden St., Denver.

CONNECTICUT: Feb. 12. Address State Board of Healing Arts, 250 Church St., New Haven.

DISTRICT OF COLUMBIA: Washington, April 17-18. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington.

FLORIDA: Gainesville, June 8. Sec., Dr. J. F. Conn, John B. Stetson University, DeLand.

NEW MEXICO: Feb. 7. Sec., Miss Pia Joerger, State Capitol, Santa Fe.

OREGON: Portland, March 4. Sec., Board of Higher Education, Mr. C. D. Byrne, University of Oregon, Eugene.

RHODE ISLAND: Providence, Feb. 16. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Vermillion, June 4-5. Sec., Dr. G. M. Evans, Yankton.

WISCONSIN: Madison, April 1. Sec., Prof. R. N. Bauer, 152 W. Wisconsin Ave., Milwaukee.

and Legislation

MEDICOLEGAL ABSTRACTS

Optometry Practice Acts: Practice by Optometrist as Employee of Corporation "Unprofessional Conduct."—Lieberman, who was licensed to practice optometry in Connecticut, occupied rooms in a department store and examined persons seeking optometrical services, making no charge for his services if the person he examined and prescribed for purchased in the store the glasses prescribed but otherwise charging a fee that was turned over to the corporation conducting the store. He was paid a salary by the corporation and also received commissions on optical goods sold on his prescription. The corporation advertised extensively regarding the optometrical services available at its store, in which advertisements Lieberman's name, if it appeared at all, appeared relatively inconspicuously. These advertisements reasonably left the impression in the minds of the readers that the corporation was offering to render optometrical services or, at least, that the corporation was responsible for the way and manner in which they were rendered. The Connecticut state board of examiners in optometry, after notice and hearing, revoked Lieberman's license to practice optometry on the ground that his practice under the circumstances stated constituted "unprofessional conduct," which under the Connecticut optometry practice act is sufficient grounds for the revocation of a license to practice optometry. Lieberman, in effect, appealed to the superior court, Hartford County, which restored his license, and the state board of examiners appealed to the Supreme Court of Errors of Connecticut.

This court, said the Supreme Court of Errors, construed the words "unprofessional conduct" as used in the optometry practice act in *Sage-Allen Co., Inc. v. Wheeler*, 119 Conn. 667, 179 A. 195, 98 A. L. R. 897, where we said:

The words must have been used in the light of the fundamental purpose of the statutes to regulate the profession in the public interest and they can only be construed as intending to include conduct within their fair purport which either shows that the person guilty of it is intellectually or morally incompetent to practice the profession or has committed an act or acts of a nature likely to jeopardize the interest of the public.

The question presented by this case is whether on the facts Lieberman could reasonably be held to be guilty of conduct "of a nature likely to jeopardize the interest of the public." In determining this question the court considered the various optometry practice acts that have been enacted in Connecticut and concluded that there has been in those acts a growing recognition of the importance of regulating optometry and a recognition that a calling that was originally regarded as a trade has increasingly taken on the aspects of a learned profession. No doubt, said the court, this recognition is due to a greater realization by the legislature and the public of the fact we stated in the *Sage-Allen* case, supra; as follows:

It is a matter of common knowledge that where a person suffers from defective vision the use of eyeglasses not correctly adapted to remedy the defect may seriously aggravate it and, because of the resultant eye strain, may bring about nervous and even physical disorders, with accompanying discomfort and loss of efficiency.

To this statement, continued the court, we add that a properly qualified optometrist should be able often to discover disease conditions of the eye which require treatment by an oculist and should, when they are discovered, refer his patient to a physician qualified to deal with them.

Lieberman apparently contended that his practice under his arrangement with the department store did not constitute unprofessional conduct because such an arrangement was permitted by the optometry practice act. The optometry practice act in effect when the *Sage-Allen* case, supra, was decided, said the court, provided, so far as is here pertinent, that "Nothing herein contained shall prohibit the operation in a department store of an optical department under the supervision of a duly licensed optometrist." By an amendment enacted in 1939 this

sentence was eliminated and the following was substituted: "No person except a licensed optometrist shall operate an optometrical office. Nothing herein contained shall be construed as prohibiting the conducting of clinics or visual surveys when they are conducted without profit." It is not easy to determine the purpose designed to be accomplished by this 1939 amendment, but we need not consider that question in its broad aspects. As was said in the Sage-Allen case, *supra*, the sentence in the law that was in effect before the 1939 amendment made it possible for a department store to conduct an optical department and employ a licensed optometrist in connection with it. It did not, in its terms or by necessary implication, authorize a department store to establish in connection with its business an office designed solely to render optometrical service and held out to the public as a place to which they might resort for such service, regardless of the relationship between a licensed optometrist in charge of such an office and the management of the store. As we said in that case, there is a distinction as regards the attention which the public is entitled to expect between a situation where an optical department in a store is in charge of a licensed optometrist and one where it is in charge of a layman, as in the former a customer visiting the department expects to receive the advice and assistance of a trained optometrist, assistance which he does not expect in the latter case. So there is a distinction as regards the rightful expectations of the public between a situation where an optometrist is merely in charge of an optical department and one where, in connection with the business of the store, a department store maintains a separate office in which an optometrist renders and is held out to the public as rendering the usual services of a licensed optometrist. Certainly the amendment of 1939 cannot be held to broaden the rights of those conducting stores where optical goods are sold so as to authorize them under any and all circumstances to have in connection with them an office where optometrical services are rendered.

While it may be true, continued the court, that the standards of professional conduct which should govern the practice of optometry are not in all respects the same as those which govern the practice of a physician, still in view of the recognized character that optometry has today there are certain fundamental requirements common to both the practice of optometry and the practice of medicine. One of these is that the patient who resorts to an optometrist for advice and help is entitled to the same undivided loyalty that he should receive from a physician. As was said in *Rowe v. Burt's Inc.*, Ohio App., 31 N. E. (2d) 725:

Professionally, an optometrist should have no interest in any way in who fills his prescriptions. It is manifestly apparent that the situation here prevailing cannot permit the freedom in the optometrists which should exist in purely professional men.

That reasoning, we take it, was the basis of the decision of the Supreme Judicial Court of Massachusetts in *McMurdo v. Getter*, 298 Mass. 363, 10 N. E. (2d) 139, where it was held that a firm which availed itself of the services of a licensed optometrist was to be regarded as practicing optometry, although the test usually employed in determining whether an agency exists was not met. The court there said that employees of corporations, "though professionally trained and duly licensed to practice, owe their primary allegiance and obedience to their employer rather than to the clients or patients of their employer," and the principle which forbids a licensed member of a profession to practice among the public as the employee of an unlicensed person or corporation "recognizes the necessity of immediate and unbroken relationship between a professional man and those who engage his services." While, continued the court, under the facts in this case it might not be concluded reasonably that Lieberman was the agent or employee of the corporation, the vice of the situation lies in the particular relationship existing between Lieberman and the corporation and certain circumstances resulting from the arrangements between them. The fact that a considerable part of the compensation received by Lieberman came from com-

missions received from the corporation based on the sale of glasses prescribed by him, if such a practice were held generally permissible, would make it likely, at least in some instances, that the welfare of the patient would not be the sole criterion applied by the optometrist in rendering services to him. Also, because the profit to the store from the arrangement would come entirely from its sale of optical goods, an optometrist under such an arrangement as the one before us, in order to preserve his position with the corporation, might well be tempted to prescribe glasses or more expensive glasses when this would not serve true interests of the patient. The situation is one where the complete loyalty of an optometrist to his patient is put into serious jeopardy.

The state board of examiners in optometry concluded that the arrangement between Lieberman and the corporation amounted to a splitting of fees, forbidden by one of its regulations. Splitting of fees, said the court, as defined in the statutes of several states occurs where a member of a profession divides the compensation he receives from a patient with another member of the same profession or any person who has sent the patient to him or has called him into consultation. It may be that Lieberman could not be charged with a splitting of fees in the usual understanding of the offense. However that may be, where an optometrist working under such an arrangement as was Lieberman is not compensated for his services by a patient who buys glasses in the store, but only by the salary and commissions paid to him by the corporation with which he is connected, and where, if the patient does not buy glasses in the store, the compensation the optometrist receives is turned over to the corporation, the practice might well impair the personal responsibility of the optometrist to his patients, which is one of the safeguards of the proper rendition of services by a member of a profession.

The court then considered the advertising of optometrical services by the corporation. The advertisements, the court held, could reasonably be regarded as creating in the public mind the impression that it was the corporation which was offering to render optometrical services, or at least it was the corporation which was responsible for the way and manner in which they were rendered. An optometrist, said the court, is not forbidden to advertise; a physician may do so provided his advertisement is not "deceptive, misleading, extravagant, improbable or untrue." General Statutes, Sup. 1941, sec. 475f. Certainly an optometrist can be held to no higher standard of conduct. But to become a party to a type of advertising such as here involved may well be regarded as "unprofessional conduct" in that it leads the public into an erroneous conception of the respective responsibilities of the corporation and the plaintiff.

The court accordingly concluded that the state board of examiners in optometry from the evidence before it could reasonably find proved the charge that Lieberman was guilty of unprofessional conduct. Accordingly the court affirmed the action of the board in revoking Lieberman's license to practice optometry.—*Lieberman v. Connecticut State Board of Examiners in Optometry*, 34 A. (2d) 213 (Conn., 1943.)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Treatment of Amebic Dysentery.—Soper began intravenous administration of emetine in amebic dysentery twenty years ago. He saw many early cases, made daily proctosigmoidoscopies and demonstrated the acute early lesions, which disappeared after the third or fourth intravenous injection of emetine. Seven consecutive daily doses were given, followed by a seven day course of acetarsone, consisting of one 0.25 Gm. tablet three times daily before meals. No toxic symptoms were observed after the emetine injections. It was always given slowly, with the patient lying down. The author had but one recurrence in a series of 302 cases. In earlier years he had given emetine in advanced cases with deep ulcerations over a period of three or four weeks and had seen toxic symptoms. This convinced him that the failure of emetine to cure the chronic carrier was due to the induration surrounding the ulcer, which acted as a barrier. Intravenous administration of emetine is highly specific for patients not in the carrier stage. It reaches the entire circulatory area in a more concentrated form than when given subcutaneously. Hepatic and pulmonary abscesses occur often in late neglected cases. Abscesses in the brain, skin, lymph glands and bladder have been reported. The late ulcerative lesions in the colon are intractable to treatment. The ulcers are frequently connected by sinuses beneath a still intact mucous membrane. The author advises chiniofon as the drug of choice in the treatment of carriers. It is given in 0.25 Gm. tablets three to four times daily (adult dosage) for a period of eight to ten days.

Peptic Ulcer.—According to Kirk peptic ulcer assumes the leading role in digestive diseases in the military service. It leads all other gastrointestinal conditions as a cause for discharge from the army. The present study was made during

the period from Oct. 1, 1942 to March 1, 1943. During this time 385 patients were admitted to the gastrointestinal section for study. Of these 385 men 50, or 12.9 per cent, were found to have peptic ulcer on clinical observation with x-ray examination. No correlation has been obtained between the gastric analysis and the severity of the ulcer complaints. Midepigastric pain occurring late at night and radiating into the back appears pathognomonic of duodenal ulcer. Intolerance to greasy foods on the part of these patients seems to be the greatest obstacle to military service. The emotional concept of the genesis of ulcer is not supported by the reported cases.

Dermatitis Venenata.—French and Halpin report results of treatment of 2,544 patients with poison ivy dermatitis observed during the summer of 1942 in the Fourth Service Command. A 5 per cent alcoholic extract of poison ivy was prepared, and thirty-two stations were furnished an adequate supply. Dermatitis venenata was most troublesome during June and July. At one training center it was the established diagnosis in 15 per cent of all dispensary patients seen during this two month period. Dilution of the concentrated extract just prior to each injection furnished a 1:10 solution. Daily hypodermic administration of gradually increasing amounts was the usual routine. In most instances a dosage of from 0.4 to 0.5 cc. of the 1:10 dilution was reached by the fourth day of therapy. Rarely was

it necessary to continue the administration longer than four or five days. The majority of the patients gave a history of having had previous dermatitis on exposure to poison ivy. Thus patch testing was not a prerequisite to the therapy. Patch testing was done in instances in which there was doubt as to the diagnosis. Of the total number of 2,544 patients 1,748 were given treatment at their dispensary. These patients remained on full duty. The 754 patients who were admitted to the hospital were unable to remain on a full duty status. The average hospital stay was 8.7 days. A comparison of therapeutic methods was made on 50 patients with lesions of near equal severity. Alternate cases were treated with alcoholic extract injections or local applications. In the group receiving alcoholic extract there was an average of 8.4 hospital days per patient. The group in which local applications of lotions and creams were used recorded an average stay of 11.3 days per patient. Of the 1,851 patients treated with alcoholic extract of poison ivy leaves 86.4 per cent received satisfactory benefit, 68 per cent being classified as good and 18.4 per cent as fair results. In the 179 patients (9.7 per cent) in whom the results were poor the lesions responded very slightly. No improvement was obtained in 33 patients (1.8 per cent) and an increase in severity was observed in 38 patients (2.1 per cent). With the exception of soreness and swelling at the site of some of the injections no reactions were observed.

Germicidal Activity of Alcohol, Hydrochloric Acid and Aluminum Potassium Sulfate.—Meyer and Vicher evaluated the effect of a 0.5 per cent solution of hydrochloric acid on the bacterial flora of the hands and arms and compared it with the effect of a solution containing 70 per cent of alcohol by volume and that of a 10 per cent solution of aluminum and potassium sulfate. Alcohol in a concentration of 70 per cent by volume was found to be an efficient germicidal agent for the bacterial flora of the skin. A 0.5 per cent solution of hydrochloric acid was found to be highly efficient also but not entirely comparable to the alcohol. Aluminum and potassium sulfate in 10 per cent aqueous solution evidently hardens the skin to such an extent that the organisms are imprisoned but not killed. They may be released after the softening of the skin which occurs when rubber gloves are worn and then removed in the subsequent scrubbing. The authors believe that either alcohol 70 per cent by volume or hydrochloric acid 0.5 per cent is sufficiently efficient to use in the presurgical preparation of the surgeon's hands and that a 0.5 per cent solution of hydrochloric acid could safely be used so as to conserve the supply of alcohol for more essential purposes. They also believe that a 0.5 per cent solution of hydrochloric acid has a true germicidal action on the bacterial flora of the skin.

Isinglass as Blood Substitute in Hemorrhage and Shock.—Taylor and his associates think that in the event of heavy casualties the supply of blood serum may be insufficient and that a blood substitute should be kept in reserve. They reported experimental studies with isinglass two years ago and now describe additional investigations with this collagen, which they produce from swim bladders of fish. They demonstrated in experiments on dogs that transfusion either with whole blood or with a solution of isinglass was relatively ineffective in the treatment of shock caused by muscle damage. The difference between the results of transfusion in acute hemorrhage and in shock is offered as evidence against the theory of local fluid loss being a primary factor in the development of shock due to muscle injury. The authors describe tests for pyrogenic and antigenic activity of isinglass. The isinglass as now prepared has a relatively mild pyrogenic action. The temperature rise is well within the limits specified in the pyrogen test of the United States Department of Public Health. Isinglass is free from antigenic action. No abnormalities have been observed in the livers and kidneys of animals which have received repeated injections of isinglass intravenously over a period of weeks. The regeneration of plasma protein after depletion caused by acute hemorrhage does not appear to be interfered with by the transfusion of isinglass solution. There is some evidence that the injected protein is utilized for building body tissue and possibly in the manufacture of plasma protein.

Clinical Use of Isinglass.—Pugsley and Farquharson administered isinglass prepared by Taylor to 61 patients at the Toronto General Hospital. They used purified, powdered isinglass in concentration of 4 to 7 per cent dissolved in isotonic solution of sodium chloride. A total of 58 intravenous administrations was given to 51 patients chiefly for the purpose of detecting pyrogenic or other toxic effects; the remaining 10 patients were given isinglass solution for the treatment of shock or hemorrhage. A febrile reaction followed in 8 instances. In no case was the fever sustained longer than a few hours. A definite chill marked the onset in two febrile reactions. The remaining patients complained of a chilly sensation. Other associated symptoms in these patients were malaise, headache and nausea. In the remaining 50 infusions of isinglass solution no unfavorable symptoms followed. Ten patients suffering from the effects of shock or severe circulatory collapse were

treated by the intravenous administration of isinglass solution. All patients responded favorably; there was no evidence that the isinglass had given rise to toxic manifestations. The dose of isinglass infused varied from 200 cc. in the case of an infant to a total of 8,800 cc during the course of three days to a patient suffering from severe burn shock.

Two and Six Hour Pregnancy Tests.—Kupperman and his associates devised a two and a six hour pregnancy test which employs rats of almost any age or weight. The two hour test is based on the hyperemic effect of urinary gonadotropins on the ovary and ovarian capsule noted two hours after intraperitoneal injection of 1.5 cc. of urine in divided doses of 0.75 cc. each. The rats may be of any age (21 to 55 days) or weight (30 to 100 Gm.) provided vaginal introitus or corpus luteum formation has not occurred. If the six hour test is performed on immature rats the end reaction is the hyperemic effect of the urinary gonadotropin on the ovary and ovarian capsule. The diagnostic feature in the adult animal is the vascularizing effect of pregnancy urine on the corpora lutea of animals injected when in diestrus or metestrus. Of 33 specimens of urine from nonpregnant individuals there was no instance of a false positive reaction. Only 2 of 48 samples of pregnancy urine gave an indecisive reaction, but the urines from these patients yielded strongly positive reactions five days later. In performing the test 3 rats are sufficient, 2 for the two hour test and 1 for the six hour test. In instances of a negative test it is advisable to inject at least 2 more animals for confirmatory data.

Sublingual Use of Testosterone.—Hurxthal deals with the results of administration of testosterone in propylene glycol-alcohol sublingually in 6 cases of hypogonadism and 1 case of hypopituitarism. In the case of hypopituitarism, testosterone in propylene glycol-alcohol solution also was rubbed into the skin of one axilla and one side of the pubic area, demonstrating its local effect. In 4 cases testosterone was given for the first time. The other patients, in whom maintenance doses of testosterone by pellet implantation, injection or oral administration had been established, were given sublingual testosterone for a comparison of its maintaining effect. The preparation was administered in sublingual doses of 1 or 2 drops, which the patient was instructed to hold there for two to three minutes without swallowing. When a larger amount was administered the patient was instructed to take portions of it at convenient times throughout the day. Three of the cases of eunuchoidism reviewed here occurred in one family. The effectiveness of testosterone in propylene glycol-alcohol administered sublingually was demonstrated. It appears that in untreated eunuchoidism two or three times as much testosterone is needed sublingually as by pellet implantation. For maintenance purposes the sublingual administration of testosterone in propylene glycol-alcohol in eunuchoid patients compares favorably with intramuscular injection of testosterone propionate in oil in some cases but not in others.

Plasma Vitamin A Level After Administration of This Vitamin in Liver Disease.—Popper and his collaborators studied the influence of various liver diseases on vitamin A tolerance curves. Tolerance tests were made on 108 patients; 71 of these had disease of the liver or biliary tract, the remaining 37 were used for comparison. It was found that in patients with liver disease the tolerance curve is much flatter than in normal persons; it parallels the degree of liver damage. It is less flattened in arrested cirrhosis without jaundice and in biliary obstruction without hepatitis than in toxic hepatitis or cirrhosis with jaundice or in biliary obstruction with secondary hepatitis. With clinical improvement the tolerance curve and the low fasting plasma vitamin A level of patients with liver damage return toward normal. By comparison of the tolerance curves with a vitamin A content of liver biopsy specimens from the same patients, by comparison of the tolerance curves before and after saturating the liver with large amounts of vitamin A and by study of the tolerance curves in conditions known to be associated with disturbed intestinal absorption, evidence was obtained that the tolerance curves are not related to the liver saturation of vitamin A but rather to the efficiency of vitamin A absorption from the intestine. The disturbed intestinal absorption of vitamin A in liver disease is not primarily related to the degree of jaundice but rather to the degree of liver damage. The authors have been unable to correct the absorption damage by the administration of various bile acid preparations. Nevertheless the possibility cannot be excluded that in liver damage the absence of some particular bile acid from the intestine is the cause of the faulty absorption of vitamin A.

Calcium and Phosphorus Metabolism in Rheumatoid Arthritis.—The occurrence of decalcification in patients with rheumatoid arthritis and of marginal lippling or osteophyte formation in persons with degenerative joint disease suggested to Ropes and her collaborators that an alteration of calcium and phosphorus metabolism might be a primary feature of these diseases. The authors studied the calcium, phosphorus and nitrogen metabolism of 9 patients with rheumatoid arthritis and 3 patients with degenerative joint disease. The results revealed that the calcium and phosphorus metabolism grossly

in patients with rheumatoid arthritis and degenerative joint disease. Detailed analysis indicated a slight tendency toward an increased rate of calcium metabolism and increased calcium excretion in patients with rheumatoid arthritis and a decreased calcium excretion in individuals with degenerative joint disease. The magnitude of the increased loss and retention, respectively, was small and may not be of importance. However, the variations from normal cannot be explained by any of the factors known to influence calcium metabolism and, although slight, may be sufficiently great to be of significance over a long period of time.

Excretion of Gonadotropic Hormone by Prepuberal and Adolescent Girls.—Catchpole and Greulich studied 4 girls at a correctional institution and 8 girls representing ambulatory cases from a tuberculosis sanatorium. Studies on 4 of the latter were repeated after a one year lapse of time. An attempt was made to obtain daily twenty-four hour urine specimens from all subjects for a period of one month at least. The subjects ranged in age from 4 years and 4 months to 14 years and 6 months. Only 1 had menstruated before the assays were made. Several of the subjects experienced first menses from one to several months after the determinations were performed. In the urine of the youngest girls either no hormone or only small quantities could be detected. In preadolescent girls hormone appeared more frequently and in larger amounts. With increasing quantities, fluctuations in day by day amounts became evident, but these did not appear to be systematic or cyclic. The pattern of gonadotropic hormone output appeared to be related more closely to developmental status than to chronological age of the subjects. Hormonal activity in girls was on generally lower level than that recorded for the fully developed adult menstrual cycle. It is suggested that this activity is to be correlated with a preovulatory phase of sexual development.

Retardation of Gastric Evacuation.—The impression is prevalent that pylorospasm results from emotions or through viscerovisceral or somatovisceral reflexes initiated by irritation of any portion of the body. It is also believed that the delay in gastric evacuation which results from such irritation is largely or entirely due to pylorospasm. Quigley and his collaborators show that much of the evidence on which these concepts rest may be questioned. They have irritated various parts of the body in unanesthetized dogs and have attempted to determine the effects not only on the pyloric sphincter but simultaneously on the motility of the pyloric antrum and duodenal bulb and on the gastric evacuation process. A series of 9 dogs were provided by the method of Meschan and Quigley with permanent cannulas giving access to the gastric and duodenal lumens. These animals were trained to lie in comfortable hammocks and to cooperate with the experimental procedures. The pyloric sphincter region (antrum, sphincter and bulb) tended to behave as a unit; in action the sphincter was similar, not contrary, to the antrum. Emotions and noxious stimuli did not produce pylorospasm but tended to inhibit the entire sphincter region; they retarded gastric evacuation. This retardation resulted from decreased antral peristalsis. The delayed evacuation was not due to pylorospasm; it developed in spite of the pyloric relaxation. The claim that pylorospasm is readily produced by emotional states or noxious bodily stimuli receives little support from this experimental study or from a critical consideration of the clinical evidence.

*Peptic Ulcer, an Endocrine Disease. J. A. Crabb.—p. 368.

Peptic Ulcer, an Endocrine Disease.—Crabb treated patients with peptic ulcer by administering 1 cc. of parathyroid extract every third day for three doses, then of 10 minims (0.6 cc.) every five to seven days for from six to twelve doses. He also used a palliative such as a bismuth and a paregoric mixture or an alkaline powder to be taken twenty or thirty minutes before the expected pain for the purpose of neutralizing the hydrochloric acid and to coat over and temporarily protect the ulcer from the eroding gastric juice. He thinks that it is not advisable to give alkalis immediately after meals at any time. They render pepsin inert and interfere or prevent the proper digestion of proteins. The diet was restricted to liquids or nourishing nonirritating soft foods for a few days and later was gradually increased in variety and quantity. Based on his experience in the use of parathyroid in the treatment of peptic ulcer in a large number of cases continuously during the last sixteen years, it is the author's opinion that peptic ulcer is an endocrine disease caused by a lack in the system of the parathyroid hormone. The treatment is therefore replacement therapy.

Actinotherapy in Children. Eva Morton.—p. 68.

Use of Sulfonamides in Measles.—Swyer studied 1,193 cases of measles with a view of determining the effects of sulfonamides. The drugs were given to 324 patients for a short period immediately after admission; the remaining 869 patients did not receive sulfonamides unless complications arose. An additional 64 cases of bronchopneumonia and 29 of otitis media which occurred in an earlier epidemic were also examined as controls in the assessment of the value of this chemotherapy in treatment as opposed to prophylaxis of complications. The results were as follows: The complication rate was reduced from 13.7 to 11.4 per cent. The average hospitalization of uncomplicated cases was reduced from 12.2 to 10.8 days, but that of all complicated cases was unaltered. The mortality of bronchopneumonia was about halved. Results of treatment of otitis media were inconclusive, but the average length of hospitalization was reduced from thirty-nine days in controls to twenty-eight days in sulfonamide treated patients. Toxic manifestations were rare and mild. The author concludes that a short prophylactic course is not worth while. Having regard to the measure of therapeutic control possible for established complications (bronchopneumonia and otitis media) it is questionable whether routine sulfonamide prophylaxis with its potential risks is desirable.

Treatment of Gunshot Fractures of Limbs.—Yudin presents experiences gained in eighteen months of war. The methods used are based on three therapeutic factors: wide surgical excision of the wound, adequate local and general use of sulfonamides and prolonged fixation in plaster. He describes the aims and technic of operations for gunshot fracture of the femur at various times after occurrence of the injury and with varied degrees of infection. When operation is undertaken within a short time the procedure is confined to the removal of foreign material and damaged or devitalized tissue. In such cases additional drainage is seldom required, but the wounds are not sutured. In treatment undertaken at a later period the method of choice is wide excision of infected and necrotic tissue and great care in mechanical cleansing, followed by free drainage. Adequate excision of muscle, so as to produce a funnel shaped aperture for drainage, is of great importance. The

excision should not be excessively wide. The removal of muscles with arteries traversing them is dangerous, and in consequence the author has advocated the lateral approach through the vastus lateralis. In 350 cases of such fractures with gross sepsis in which he operated he has not had 1 single case of nonunion of the fracture. In addition, owing to the use of incision through the vastus lateralis and the technic of suturing the skin to the fascia lata he has not seen defective movement of the limb which can be attributed to postoperative defect in muscles. The first task in the treatment of a wounded man is to prevent the loss of life and limb by infection. The procedures described are often tedious and time consuming, and it has been said that such treatment cannot be used when the number of patients is large. However, they are irreplaceable by any other method of therapy, and by their means 95 per cent of patients with these injuries have their lives and limbs saved. Other methods and splinting, though useful for transport, are unsuitable for immobilization treatment over any length of time and cannot replace the use of plaster. Inadequate excision and temporary splintings could be justified only under conditions of great stress to enable the patient to be transported from the front line to the hospital.

Premature Rupture of Membranes.—Greig reports 320 cases of premature rupture of membranes occurring in a consecutive series of 2,149 deliveries conducted in a wartime emergency maternity hospital in the years 1940 to 1942. Premature rupture of membranes is defined as having taken place when the rupture of the membranes precedes labor pains. In order to have two fairly comparable series the author eliminated 159 cases with highly abnormal conditions such as antepartum hemorrhage, surgical inductions and fetal deformities. There remained for comparison (1) a series of 310 cases of premature rupture of the membranes and (2) a series of 1,680 cases of orthodox labor. Only cases of over thirty-six weeks' gestation are considered. There is a definite increase in the incidence of premature rupture of membranes in cases of abnormal presentations such as occipitoposterior, breech and twin presentations. Parity and toxemia are not factors in producing premature rupture of membranes. On the average the length of labor is not increased. In 60 per cent of cases the premature rupture of membranes and the onset of labor are clinically simultaneous. Labor is appreciably shorter than normal in this class of case. When there is delay in the onset of labor after loss of liquor amnii, labor is appreciably longer and there is a noteworthy increase in the incidence of prolonged labor over thirty hours. Here probably is the justification for the old concept of "dry labor." Intervention can be kept at least to normal limits in cases of premature rupture of membranes. Good results can be obtained by careful management.

*Infantile Paralysis: Study of a Recent Epidemic in Argentina. D. Vivoli and N. S. Loizaga.—p. 1940.

Infantile Paralysis.—An epidemic of an infectious disease presenting clinical features of poliomyelitis occurred in Argentina during the period 1942-1943. The incidence was higher in infancy and childhood and the clinical manifestations were essentially those of an acute infectious illness followed by partial or complete muscular paralysis affecting predominantly the limbs. Forms of spinal, bulbar and encephalitic poliomyelitis were clinically recognized. A number of patients died, and in the microscopic examination Vivoli and Loizaga found spherical or falciform corpuscles, sized 2.5 to 4.5 microns, located in the extracellular spaces and in the cytoplasm of macrophagic cells of the spinal cord, medulla, oblongata, intumescence, brain, liver, intestine and lymph nodes. Fragments of the spinal cord of 2 patients injected intraperitoneally or by mouth into rabbits and guinea pigs caused the death of these animals in a few days. Some of the animals developed paralyzes of the limbs. Pathologic examination showed in the organs of the inoculated animals the presence of the same corpuscles found in the patients. By their morphologic characteristics these small corpuscles were considered to be protozoan organisms, most likely toxoplasma. Attempts to cultivate the micro-organisms failed. According to Vivoli and Loizaga it is impossible to ascertain whether the epidemic was one of poliomyelitis, although the clinical symptoms in all cases were indistinguishable from those of poliomyelitis observed in previous outbreaks in Argentina.

Meningitis Due to Pfeiffer Bacillus.—Schwarzenberg and Montero Sierra report 6 cases of acute purulent meningitis due to *Haemophilus influenzae*. The meningeal symptoms appeared in the course of inflammation of the respiratory tract. The therapy consisted of administration of sulfonamide preparations in daily doses of 0.30 Gm. of the drug per kilogram of weight and of blood transfusion. It failed in all cases but 1. *Haemophilus influenzae* was identified in the cerebrospinal fluid obtained by ventricular puncture in the course of sulfonamide therapy and shortly before death. It was identified also in the cerebrospinal fluid obtained by lumbar puncture in some cases. Necropsy revealed a diffuse fibrinous purulent leptomeningitis, blockage of ventricles, encephalitis, cerebral abscesses and in some cases purulent pleurisy and septicemia.

Treatment of Suppurative Inflammation of Knee Joint.—Westhues and Rüd emphasize the importance of radical surgical intervention in cases of suppurative inflammation of knee joint. In wartime surgeons should make a rule that Låwen's method of frontal resection of the condyle or the even more radical method of resection of knee joint should be practiced. The latter method should be economically performed by chiseling off a narrow disk of bony cartilage from the condyle of the femur, including particularly the posterior parts of the condyle. Less radical intervention will not prevent stiffness of

the knee but will be associated with much more danger for the leg and the life of the wounded. Puncture should be strictly limited to early cases of blood extravasation or effusion. Radical incisions at the four edges of the joint at the same time and continuous irrigation immediately after the incisions were made may be practiced only in cases of pseudophlegmon in the presence of collateral edema associated with empyema of the knee joint, but irrigation should be discontinued if total empyema does not disappear within a very short time. The method of opening up the knee joint will provide escape of pus but requires an acute angled position of the knee which may be impossible, owing to additional wounds of the leg. Conservatism should be the rule with regard to indications for amputation. The problem of saving the leg is first and foremost a problem of adequate postoperative immobilization which will provide control of suppuration and will facilitate change of dressing. A gravitation abscess may make treatment more difficult but need not be considered as indication for amputation, whereas an erysipelatosus phlegmon should be. Blood transfusions, acid diet and exposure to air and sunlight may help to avoid amputation. Amputation may be indicated in cases in which the general condition has become worse in spite of local improvement and should be performed in the presence of local or general septic symptoms before the clinical picture of sepsis has been developed. Conservatism with regard to amputation does not entail an increase in the mortality rate.

Changes in Stored Placental Blood.—Ellenbeck and Carlblom state that stored blood of the umbilical cord undergoes certain changes and that its value compared to that of fresh blood is reduced. Its behavior has been the same as that of stored donor blood. For the first fourteen days changes in stored placental blood have been less definite than is reported in the literature with regard to stored donor blood. That applies to the disappearance of neutrophil leukocytes, to the behavior of the albumin-globulin quotient and to the increase of the potassium content of plasma.

Insulin Therapy of Carcinoma.—In the treatment of 25 patients with carcinoma, Schulte and Schütz employed Brüning's method, consisting of the administration of protamine zinc insulin combined with a low carbohydrate diet. Continuous blood sugar examinations were performed but proved of little value, since the blood sugar level did not reflect accurately the local or general effect of insulin on the organism afflicted with tumor. A high degree of tolerance to insulin similar to that in old persons with diabetes mellitus could not be demonstrated. Pronounced susceptibility to insulin of emaciated patients with carcinoma placed on a liquid-pulp diet corresponded to that of lean patients with diabetes mellitus on a low diet, as experienced by American authors. Euphoria has been the prominent characteristic of the effect of insulin therapy in carcinoma. Psychic ups and downs, however, have been observed, but these may be due to difference in the absorption rapidity of protamine zinc insulin. An objective direct effect on the tumor could not be demonstrated on roentgenologic examination, although an improvement of deglutition was manifest in cases of carcinoma of the esophagus which reacted to insulin. Complete failure of insulin was found in a case of carcinoma of the cardia in which no subjective or objective improvement could be demonstrated. The temporary analgesic effect of insulin resulted in almost complete disappearance of pain in a few cases and in a peculiar, somewhat dull pain in others; but pain became even worse when insulin therapy was discontinued. An analgesic effect was not manifest in some cases in which cancer was demonstrated on microscopic examination. Increase in appetite was noted in some patients with a resulting increase in weight of from 1 to 2 Kg., but considerable loss in weight was likewise associated with good appetite and large food intake. The peak of the insulin effect occurred within eight to ten days and was occasionally prolonged for two months. A true palliative effect cannot be attributed to insulin therapy of carcinoma. Roentgen therapy was practiced after insulin therapy, but tolerance to roentgen rays did not improve and a definite effect on the tumor could not be demonstrated. Insulin therapy may be only occasionally employed to alleviate pain and to improve a depressive mood in patients with carcinoma.

Book Notices

Traffic in Opium and Other Dangerous Drugs for the Year Ended December 31, 1942. Report by the Government of the United States of America. U. S. Treasury Department, Bureau of Narcotics. Cloth. Pp. 66, with 3 illustrations. Washington, D. C.: Government Printing Office, 1943.

This document, covering the calendar year 1942, constitutes the report of the government of the United States on the traffic in opium and other dangerous drugs for distribution through the Secretary of State to the nations signatory to the international drug conventions of 1912 and 1931. According to the report, reserve supplies of opium now stored in this country are ample to fill medical and scientific needs for several years. The number of nonmedical drug addicts in this country is estimated at no more than 1 in every 3,000 of the population, a reduction of at least 66 per cent in the past two decades. Vigilance must be exercised, however, to maintain this ratio of reduction, since war conditions frequently beget a relaxation of drug control, as has already occurred in Iran. In its analysis of the illicit traffic in narcotics, the Bureau of Narcotics records in this report that, along with Iran and Cuba, Mexico has now become the principal source of smuggled drugs seized in the illicit traffic throughout the United States. On the Mexican border, seizures of smoking opium were thirty times as large as in 1941, the major seizure during the year consisting of 27 pounds 3 ounces taken from a Mexican at Yuma, Ariz. Morphine, which formerly ranked next to heroin as a favorite drug of addiction, was extremely scarce. There were limited quantities of morphine sulfate available at extremely high prices, but morphine hydrochloride, with the exception of two seizures in Texas, was practically nonexistent on the illicit market. Heroin was obtainable in some sections of the country at very high prices but was often so highly adulterated as to be almost valueless so far as the maintenance of addiction was concerned. As a result of bootleg sources being greatly diminished there was an increased trend toward robberies and thefts from physicians' offices and drug stores. The adoption of measures to safeguard these supplies is urged by the Bureau of Narcotics. In states which permit the sale of paregoric without prescriptions, addicts purchase the drug in increasingly larger amounts and with accelerated frequency. By what might be designated a "cracking process," opium may be salvaged from paregoric, which the addict uses by hypodermic injection or orally. Compared with Canada, where the retail sale of paregoric is limited to prescriptions, the per capita consumption of this preparation in the United States is about fifteen times as high. The bureau recommends that the sale of paregoric be placed on a prescription basis. In the opinion of the bureau the most troublesome type of diversion of narcotic drugs from legitimate channels is that represented by the sale of morphine or of so-called morphine prescriptions by the relatively few unethical physicians who for financial gain descend to the level of and replace the drug pedler. Reference in detail is made to the case of one physician who issued 1,696 prescriptions between July 1, 1941 and Sept. 23, 1942 calling for a total of 37,602 $\frac{1}{4}$ grain morphine tablets. In addition, this physician purchased on official order forms 7,000 $\frac{1}{4}$ grain morphine tablets, making a total of 44,602 tablets dispensed or prescribed. This physician practiced in a small town with a population of 425. The total quantity of morphine seized during the year was 137 ounces, as compared with 96 ounces seized in 1941; of heroin, 879 ounces as compared with 922 ounces; of cocaine, only 4 ounces as compared with 15 ounces; of smoking opium, 1,851 ounces 161 grains (1941 figures not given); of marihuana, 11,830 ounces of bulk marihuana and 32,817 marihuana cigarettes (comparable 1941 figures not given). The bureau takes issue with the contention recently advanced that marihuana does not give rise to antisocial behavior and cites authorities in support of its views. Three establishments were authorized to use raw opium during the year for manufacturing medicinal, powdered and granulated opium and for extracting alkaloids for sale or export as such. A fourth establishment was authorized to use raw opium in the extracting of alkaloids for use exclusively in the manufac-

ture of its specialty. Four additional establishments were authorized to procure and use comparatively small quantities of raw opium for the purpose of manufacturing medicinal opium, tinctures and extracts. Two establishments were authorized to import coca leaves for the purpose of producing cocaine, one of which was authorized in addition to import a supply of coca leaves for the purpose of manufacturing therefrom a non-narcotic flavoring extract. The report concludes with a number of tables reflecting the results of law enforcement activities engaged in during the year.

Textbook of Midwifery. By Wilfred Shaw, M.A., M.D., F.R.C.S., Physician-Accoucheur in Charge of Out-Patients, St. Bartholomew's Hospital, London. Fabrikoid. Price, 21s. Pp. 588, with 246 illustrations. London: J. & A. Churchill, Ltd., 1943.

This is an outgrowth of the author's lectures and instruction to medical students at St. Bartholomew's Hospital. The material is well organized and presented logically and clearly. It should serve as an admirable textbook for students and practitioners. Although there is a considerable difference in the practice of obstetrics in the United States and Great Britain, fundamental conditions remain the same. Most of the normal cases are under the care of midwives in England, and the majority of women are delivered by general practitioners in this country. For these reasons the author suggests a careful screening of patients so that parturition can be kept as natural as possible in normal women; but when complications arise they should be managed by competent specialists. This textbook, in common with most books in the specialty, retains many time honored practices that have been made obsolete by the advances in medicine and the development of safer and better procedures. The introduction of ergonovine has made obsolete the use of a hot intrauterine douche for the treatment of post-partum hemorrhage as a result of uterine atony. The premature induction of labor for cephalopelvic disproportion is still advocated by the author, but in the United States this procedure has been entirely replaced by trial labor and the low or cervical cesarean section in case of failure. In the treatment of placenta previa, uterine and vaginal tamponades are dangerous and have no place in modern obstetrics. The use of a bag and perhaps Braxton Hick's version is rapidly being replaced by safer procedures. On the other hand, the use of sulfonamides prophylactically in difficult deliveries represents a modern approach to the treatment of infections which may have some virtue. The author is to be congratulated on writing an excellent textbook during so critical a period in the life of his country.

An Introduction to Sociology and Social Problems: A Textbook for Nurses. By Deborah MacLurg Jensen, R.N., B.Sc., M.A., Instructor in Sociology and Social Problems at Schools of Nursing of St. Louis City Hospital and St. Luke's Hospital, St. Louis. Second edition. Cloth. Price, \$3.25. Pp. 420, with 78 illustrations. St. Louis: C. V. Mosby Company, 1943.

This textbook for nurses, first published in 1939, follows the same general pattern as the first edition but has been completely rewritten. It is organized into eleven units. Unit I consists of one chapter concerned with the orientation of the nurse in a changing society. Unit II has three chapters dealing respectively with personality development, social groups and racial and nationality groups. In unit III are seven chapters dealing with social institutions, including the family, religious, economic and governmental institutions, professional nursing as a social institution and the interdependence of social institutions. Unit IV contains four chapters dealing with community organizations of various kinds and the place of the nurse in relation to them. Unit V consists of two chapters dealing with social change. A single chapter comprises unit VI, having to do with social problems in nursing service. Unit VII is composed of four chapters dealing with social problems arising from biologic sources, that is disease and physical deficiency; in this unit is a chapter on medical social work. Unit VIII deals in one chapter with mental diseases, mental hygiene and nursing. In unit IX are two chapters about social problems from economic sources. Unit X discusses social problems from cultural sources, devoting one chapter each to child welfare, the aged, crime and miscellaneous problems. Unit XI deals in three chap-

The incidence was higher in infancy and childhood and the clinical manifestations were essentially those of an acute infectious illness followed by partial or complete muscular paralysis affecting predominantly the limbs. Forms of spinal, bulbar and encephalitic poliomyelitis were clinically recognized. A number of patients died, and in the microscopic examination Vivoli and Loizaga found spherical or falciform corpuscles, sized 2.5 to 4.5 microns, located in the extracellular spaces and in the cytoplasm of macrophagic cells of the spinal cord, medulla, oblongata, intumescence, brain, liver, intestine and lymph nodes. Fragments of the spinal cord of 2 patients injected intraperitoneally or by mouth into rabbits and guinea pigs caused the death of these animals in a few days. Some of the animals developed paralyzes of the limbs. Pathologic examination showed in the organs of the inoculated animals the presence of the same corpuscles found in the patients. By their morphologic characteristics these small corpuscles were considered to be protozoan organisms, most likely toxoplasma. Attempts to cultivate the micro-organisms failed. According to Vivoli and Loizaga it is impossible to ascertain whether the epidemic was one of poliomyelitis, although the clinical symptoms in all cases were indistinguishable from those of poliomyelitis observed in previous outbreaks in Argentina.

Meningitis Due to Pfeiffer Bacillus.—Schwarzenberg and Montero Sierra report 6 cases of acute purulent meningitis due to *Haemophilus influenzae*. The meningeal symptoms appeared in the course of inflammation of the respiratory tract. The therapy consisted of administration of sulfonamide preparations in daily doses of 0.30 Gm. of the drug per kilogram of weight and of blood transfusion. It failed in all cases but 1. *Haemophilus influenzae* was identified in the cerebrospinal fluid obtained by ventricular puncture in the course of sulfonamide therapy and shortly before death. It was identified also in the cerebrospinal fluid obtained by lumbar puncture in some cases. Necropsy revealed a diffuse fibrinous purulent leptomeningitis, blockage of ventricles, encephalitis, cerebral abscesses and in some cases purulent pleurisy and septicemia.

the knee but will be associated with much more danger for the leg and the life of the wounded. Puncture should be strictly limited to early cases of blood extravasation or effusion. Radical incisions at the four edges of the joint at the same time and continuous irrigation immediately after the incisions were made may be practiced only in cases of pseudophlegmon in the presence of collateral edema associated with empyema of the knee joint, but irrigation should be discontinued if total empyema does not disappear within a very short time. The method of opening up the knee joint will provide escape of pus but requires an acute angled position of the knee which may be impossible, owing to additional wounds of the leg. Conservatism should be the rule with regard to indications for amputation. The problem of saving the leg is first and foremost a problem of adequate postoperative immobilization which will provide control of suppuration and will facilitate change of dressing. A gravitation abscess may make treatment more difficult but need not be considered as indication for amputation, whereas an erysipelatous phlegmon should be. Blood transfusions, acid diet and exposure to air and sunlight may help to avoid amputation. Amputation may be indicated in cases in which the general condition has become worse in spite of local improvement and should be performed in the presence of local or general septic symptoms before the clinical picture of sepsis has been developed. Conservatism with regard to amputation does not entail an increase in the mortality rate.

Changes in Stored Placental Blood.—Ellenbeck and Carlblom state that stored blood of the umbilical cord undergoes certain changes and that its value compared to that of fresh blood is reduced. Its behavior has been the same as that of stored donor blood. For the first fourteen days changes in stored placental blood have been less definite than is reported in the literature with regard to stored donor blood. That applies to the disappearance of neutrophil leukocytes, to the behavior of the albumin-globulin quotient and to the increase of the potassium content of plasma.

Insulin Therapy of Carcinoma.—In the treatment of 25 patients with carcinoma, Schulte and Schütz employed Brüning's method, consisting of the administration of protamine zinc insulin combined with a low carbohydrate diet. Continuous blood sugar examinations were performed but proved of little value, since the blood sugar level did not reflect accurately the local or general effect of insulin on the organism afflicted with tumor. A high degree of tolerance to insulin similar to that in old persons with diabetes mellitus could not be demonstrated. Pronounced susceptibility to insulin of emaciated patients with carcinoma placed on a liquid-pulp diet corresponded to that of lean patients with diabetes mellitus on a low diet, as experienced by American authors. Euphoria has been the prominent characteristic of the effect of insulin therapy in carcinoma. Psychic ups and downs, however, have been observed, but these may be due to difference in the absorption rapidity of protamine zinc insulin. An objective direct effect on the tumor could not be demonstrated on roentgenologic examination, although an improvement of deglutition was manifest in cases of carcinoma of the esophagus which reacted to insulin. Complete failure of insulin was found in a case of carcinoma of the cardia in which no subjective or objective improvement could be demonstrated. The temporary analgesic effect of insulin resulted in almost complete disappearance of pain in a few cases and in a peculiar, somewhat dull pain in others; but pain became even worse when insulin therapy was discontinued. An analgesic effect was not manifest in some cases in which cancer was demonstrated on microscopic examination. Increase in appetite was noted in some patients with a resulting increase in weight of from 1 to 2 Kg., but considerable loss in weight was likewise associated with good appetite and large food intake. The peak of the insulin effect occurred within eight to ten days and was occasionally prolonged for two months. A true palliative effect cannot be attributed to insulin therapy of carcinoma. Roentgen therapy was practiced after insulin therapy, but tolerance to roentgen rays did not improve and a definite effect on the tumor could not be demonstrated. Insulin therapy may be only occasionally employed to alleviate pain and to improve a depressive mood in patients with carcinoma.

Treatment of Suppurative Inflammation of Knee Joint.—Westhues and Rüd emphasize the importance of radical surgical intervention in cases of suppurative inflammation of knee joint. In wartime surgeons should make a rule that Lawen's method of frontal resection of the condyle or the even more radical method of resection of knee joint should be practiced. The latter method should be economically performed by chiseling off a narrow disk of bony cartilage from the condyle of the femur, including particularly the posterior parts of the condyle. Less radical intervention will not prevent stiffness of

Traffic in Opium and Other Dangerous Drugs for the Year Ended December 31, 1942. Report by the Government of the United States of America. U. S. Treasury Department, Bureau of Narcotics. Cloth. Pp. 66, with 3 illustrations. Washington, D. C.: Government Printing Office, 1943.

This document, covering the calendar year 1942, constitutes the report of the government of the United States on the traffic in opium and other dangerous drugs for distribution through the Secretary of State to the nations signatory to the international drug conventions of 1912 and 1931. According to the report, reserve supplies of opium now stored in this country are ample to fill medical and scientific needs for several years. The number of nonmedical drug addicts in this country is estimated at no more than 1 in every 3,000 of the population, a reduction of at least 66 per cent in the past two decades. Vigilance must be exercised, however, to maintain this ratio of reduction, since war conditions frequently beget a relaxation of drug control, as has already occurred in Iran. In its analysis of the illicit traffic in narcotics, the Bureau of Narcotics records in this report that, along with Iran and Cuba, Mexico has now become the principal source of smuggled drugs seized in the illicit traffic throughout the United States. On the Mexican border, seizures of smoking opium were thirty times as large as in 1941, the major seizure during the year consisting of 27 pounds 3 ounces taken from a Mexican at Yuma, Ariz. Morphine, which formerly ranked next to heroin as a favorite drug of addiction, was extremely scarce. There were limited quantities of morphine sulfate available at extremely high prices, but morphine hydrochloride, with the exception of two seizures in Texas, was practically nonexistent on the illicit market. Heroin was obtainable in some sections of the country at very high prices but was often so highly adulterated as to be almost valueless so far as the maintenance of addiction was concerned. As a result of bootleg sources being greatly diminished there was an increased trend toward robberies and thefts from physicians' offices and drug stores. The adoption of measures to safeguard these supplies is urged by the Bureau of Narcotics. In states which permit the sale of paregoric without prescriptions, addicts purchase the drug in increasingly larger amounts and with accelerated frequency. By what might be designated a "cracking process," opium may be salvaged from paregoric, which the addict uses by hypodermic injection or orally. Compared with Canada, where the retail sale of paregoric is limited to prescriptions, the per capita consumption of this preparation in the United States is about fifteen times as high. The bureau recommends that the sale of paregoric be placed on a prescription basis. In the opinion of the bureau the most troublesome type of diversion of narcotic drugs from legitimate channels is that represented by the sale of morphine or of so-called morphine prescriptions by the relatively few unethical physicians who for financial gain descend to the level of and replace the drug pedler. Reference in detail is made to the case of one physician who issued 1,696 prescriptions between July 1, 1941 and Sept. 23, 1942 calling for a total of 37,602 $\frac{1}{4}$ grain morphine tablets. In addition, this physician purchased on official order forms 7,000 $\frac{1}{4}$ grain morphine tablets, making a total of 44,602 tablets dispensed or prescribed. This physician practiced in a small town with a population of 425. The total quantity of morphine seized during the year was 137 ounces, as compared with 96 ounces seized in 1941; of heroin, 879 ounces as compared with 922 ounces; of cocaine, only 4 ounces as compared with 15 ounces; of smoking opium, 1,851 ounces 161 grains (1941 figures not given); of marihuana, 11,830 ounces of bulk marihuana and 32,817 marihuana cigarettes (comparable 1941 figures not given). The bureau takes issue with the contention recently advanced that marihuana does not give rise to antisocial behavior and cites authorities in support of its views. Three establishments were authorized to use raw opium during the year for manufacturing medicinal; powdered and granulated opium and for extracting alkaloids for sale or export as such. A fourth establishment was authorized to use raw opium in the extracting of alkaloids for use exclusively in the manufac-

ture of its specialty. Four additional establishments were authorized to procure and use comparatively small quantities of raw opium for the purpose of manufacturing medicinal opium, tinctures and extracts. Two establishments were authorized to import coca leaves for the purpose of producing cocaine, one of which was authorized in addition to import a supply of coca leaves for the purpose of manufacturing therefrom a non-narcotic flavoring extract. The report concludes with a number of tables reflecting the results of law enforcement activities engaged in during the year.

Textbook of Midwifery. By Wilfred Shaw, M.A., M.D., F.R.C.S., Physician-Accoucheur in Charge of Out-Patients, St. Bartholomew's Hospital, London. Fabrikoid. Price, 21s. Pp. 588, with 246 illustrations. London: J. & A. Churchill, Ltd., 1943.

This is an outgrowth of the author's lectures and instruction to medical students at St. Bartholomew's Hospital. The material is well organized and presented logically and clearly. It should serve as an admirable textbook for students and practitioners. Although there is a considerable difference in the practice of obstetrics in the United States and Great Britain, fundamental conditions remain the same. Most of the normal cases are under the care of midwives in England, and the majority of women are delivered by general practitioners in this country. For these reasons the author suggests a careful screening of patients so that parturition can be kept as natural as possible in normal women; but when complications arise they should be managed by competent specialists. This textbook, in common with most books in the specialty, retains many time honored practices that have been made obsolete by the advances in medicine and the development of safer and better procedures. The introduction of ergonovine has made obsolete the use of a hot intrauterine douche for the treatment of post-partum hemorrhage as a result of uterine atony. The premature induction of labor for cephalopelvic disproportion is still advocated by the author, but in the United States this procedure has been entirely replaced by trial labor and the low or cervical cesarean section in case of failure. In the treatment of placenta previa, uterine and vaginal tamponades are dangerous and have no place in modern obstetrics. The use of a bag and perhaps Braxton Hick's version is rapidly being replaced by safer procedures. On the other hand, the use of sulfonamides prophylactically in difficult deliveries represents a modern approach to the treatment of infections which may have some virtue. The author is to be congratulated on writing an excellent textbook during so critical a period in the life of his country.

An Introduction to Sociology and Social Problems: A Textbook for Nurses. By Deborah MacLurg Jensen, R.N., B.Sc., M.A., Instructor in Sociology and Social Problems at Schools of Nursing of St. Louis City Hospital and St. Luke's Hospital, St. Louis. Second edition. Cloth. Price, \$3.25. Pp. 420, with 78 illustrations. St. Louis: C. V. Mosby Company, 1943.

This textbook for nurses, first published in 1939, follows the same general pattern as the first edition but has been completely rewritten. It is organized into eleven units. Unit I consists of one chapter concerned with the orientation of the nurse in a changing society. Unit II has three chapters dealing respectively with personality development, social groups and racial and nationality groups. In unit III are seven chapters dealing with social institutions, including the family, religious, economic and governmental institutions, professional nursing as a social institution and the interdependence of social institutions. Unit IV contains four chapters dealing with community organizations of various kinds and the place of the nurse in relation to them. Unit V consists of two chapters dealing with social change. A single chapter comprises unit VI, having to do with social problems in nursing service. Unit VII is composed of four chapters dealing with social problems arising from biologic sources, that is disease and physical deficiency; in this unit is a chapter on medical social work. Unit VIII deals in one chapter with mental diseases, mental hygiene and nursing. In unit IX are two chapters about social problems from economic sources. Unit X discusses social problems from cultural sources, devoting one chapter each to child welfare, the aged, crime and miscellaneous problems. Unit XI deals in three chap-

"Differential Diagnosis.—The cerebrospinal fluid findings in cases of myxedema may be very similar to those of brain tumor, i. e., an increased pressure and a high protein content. The differential diagnosis is not always possible from the cerebrospinal fluid findings. The estimation of the basal metabolic rate is important in such cases."

The reference to Thompson et al. is Thompson, Phebe K.; Silveus, Esther, and Dailey, Mary E.: The Cerebrospinal Fluid in Myxedema, *Arch. Int. Med.* 44:368 (Sept.) 1929.

An increase in protein in the spinal fluid and the resultant changes in colloidal curves, whether gold or other, are entirely nonspecific so far as a diagnosis of neurosyphilis is concerned. The only specific change produced by syphilis in the spinal fluid is a positive Wassermann or flocculation reaction. Increased protein content and colloidal changes may be due to a wide variety of other diseases.

UNDESCENDED TESTES

To the Editor:—I am attempting to obtain the consensus regarding the value of chorionic gonadotropin injections in cryptorchism. I treated a patient aged 10 whose height, weight and general condition were normal except for failure of descent of the right testis. The right testis was not palpable; the left was in the scrotal sac and was normal in size. He received injections of 100 units of chorionic gonadotropin three times weekly for a total of eighty injections (8,000 units). About midway in this therapy the right testis became palpable in the lower part of the inguinal canal. Toward the end of the therapy the testis would almost reach the scrotal sac, but on palpation it would recede. There was some increase in size since it was first palpable, but it still was smaller than the left. Four years later (three years after conclusion of therapy) he was operated on for right cryptorchism. I saw him again recently, one year postoperatively, and his right testis is palpable at the top of the scrotal sac, recedes on palpation and is smaller than the left. I have advised further hypodermic medication. The surgeon ridicules the suggestion, as he also ridiculed the original therapy. Was the original therapy wrong? I understand this to be the proper preoperative procedure. Is it advisable to resume gonadotropin medication now in order to increase the size of the testis and help bring it down into proper position in the scrotal sac?

M. C. Rosenkrantz, M.D., New York.

ANSWER:—It is generally agreed by those who have done considerable clinical investigation on the effect of endocrine therapy in producing descent of testes that this form of treatment in the human being will bring down not more than 25 per cent of the total number of undescended testes.

The original therapy was not wrong. It would appear that further endocrine therapy with chorionic gonadotropin 500 international units three times a week might be indicated for a short period of time—possibly eight weeks. If the testis does not descend by the time, another surgical attempt should be made to place it definitely in the scrotum. It is doubtful whether endocrine therapy will increase the size of the testes.

NERVE INJURY FROM BITE OF BEAR

To the Editor:—A man was bitten by a bear in Yellowstone one year ago, the teeth penetrating the skin of the upper thumb, forefinger and left cutaneous fold. Healing occurred promptly without infection or medical attention. Two months later the patient had a mild febrile attack simulating a light influenza. Following this a general decline in health and a loss of weight were suffered. Tonsillectomy was performed six months later on the advice of the family physician. There followed a slow but moderate general improvement. Meanwhile and continuing to date a loss of strength has occurred in the left thumb and forefinger with pronounced atrophy of the muscles involved. Could you throw some light on this whole affair, especially now with reference to the loss of function of the two digits?

David P. Ferris, M.D., St. Louis.

ANSWER:—This man probably has an atrophy of the first dorsal interosseus muscle on the left side due to an injury of its nerve supply, that is, muscular branch of the left ulnar nerve. Of course the extensors and flexors of the thumb and index fingers may also have been injured. The query does not mention the exact muscles involved. The atrophy and weakness of the thumb and index finger are due to the original bear bite.

PREGNANCY AND ABORTION

To the Editor:—A woman had a miscarriage in August 1943 during the first part of the third month of her first pregnancy. Before her pregnancy an obstetrician said she was normal internally and it would be easy for her to become pregnant. What should be done to prevent future miscarriages? Are hormones required? The patient has had two normal periods since her miscarriage. How soon would it be safe to try for the second pregnancy?

M.D., New Mexico.

ANSWER:—It is not unusual for the first pregnancy to end in abortion, even though the pelvic organs are entirely normal. In many instances the embryo or its covering are abnormal. As a rule, no special precautions are necessary during the next pregnancy. It may be well to have a basal metabolism deter-

mination and, if the rate is subnormal, thyroid can be administered during the first half of the gestation. Stimuli, such as coitus, douches and cathartics, should be avoided during the first three months of the gestation. Although many obstetricians suggest an interval of at least six months between pregnancies, there is no good proof that this is necessary.

Patients who have had several abortions and no viable offspring may be placed on a special regimen, which may include progesterone and vitamin E in the form of tocopherols.

THERAPY OF ALCOHOLISM

To the Editor:—What dosage of apomorphine is necessary to produce nausea (or even vomiting) if this drug is placed in alcoholic drinks? I have a patient who is drinking too much at present and it was my idea to produce a nausea by having his wife put apomorphine in his drinks. This was tried on several occasions without success. In one evening a total of 3/10 grain (0.02 Gm.) was used without success. Is this plan advisable? Is it necessary to use larger doses than the usual 1/10 grain (0.0065 Gm.)? Will this drug work effectively by mouth?

M.D., Indiana.

ANSWER:—The action of apomorphine by mouth is so variable and the beneficial results are so doubtful that this form of treatment is not advised. Even when administered by injection, apomorphine has too short a phase of nausea to form a strong and lasting association between the drinking of liquor and the ensuing illness. Also the drug may act as a powerful narcotic causing sleep, which often blots out the memory of discomfort; or it may cause euphoria, which is certainly not conducive to the desired conditioned reflex. These facts are pointed out by Voegtlin, Lamere and Broz (*Quart. J. Stud. Alc.* 1:501 [Dec.] 1940), who call attention to the danger and futility of using apomorphine in this way. They recommend the injection of emetine followed by the exhibition of a variety of alcoholic drinks, the dosage of emetine and timing being adjusted so that nausea will follow the sight, smell and taste of liquor.

HAZARDS FROM SILICON AND FLUORIDES

To the Editor:—In a steel factory the question has arisen as to certain occupational hazards. The compound CaSi_2 containing 3 per cent excess silicon metal is used as a reducing agent for electric furnace slags. The compound must be ground before using. The grinding operation raises a considerable amount of dust of the material. Can this have any injurious effect on the workers? The electric furnace process is accompanied by the production of clouds of the following materials: Fe_2O_3 , SiF_4 , F_2 , CaC_2 and SO_2 . The fluorine compounds can be detected by their characteristic irritating odor, but aside from causing temporary discomfort there is no other obvious effect on the men. Would constant inhalations of any of these materials cause any ill effects? Some of the men develop skin eruptions on the wrists and ankles. Could this be due to exposure to burnt lime (CaO)?

I. T. Zeckwer, M.D., Philadelphia.

ANSWER:—No specific information is available on the physiologic action of CaSi_2 , but in general silicides like carbides (except calcium carbide) are comparatively inert materials. Fluorine is a recognized pulmonary irritant. The gas silicon tetrafluoride, on contact with water, forms hydrofluosilicic acid, but this is not noticeably irritating unless heated. All of these products liberated as fumes in the process described should be regarded as possible acute irritants. Whether they cause progressive chronic disease of the skin or respiratory tract is unknown.

FETAL ASPHYXIA

To the Editor:—I was called to attend a woman in pregnancy who, to the best calculation, was in the seventh month of gestation. She was in pain but not of the rhythmic type of labor. Examination disclosed the amniotic sac presenting intact with the head palpable. No dilated uterine cervix could be found. The membrane was ruptured and the labor terminated in a few minutes, with a little manipulation. An asphyxiated child was delivered with cessation of heart beat. On exposure to the air its fingers twitched a little, showing that death was recent. The cord was severed immediately but did not bleed. No time was lost in making a uterine examination, which disclosed a contracted cervix and retained placenta therein. This was removed by disintegration with some difficulty. This is what had happened: The fetus with the membrane had been expelled from the uterus and had remained in the vagina while the uterus had clamped down on this placenta, thereby cutting off the circulation of blood to the fetus, which caused the asphyxiation. I have carefully searched the literature and cannot find any parallel case. Will you please tell me if there is any such case on record?

T. H. Standlee, M.D., Mirando City, Texas.

ANSWER:—In all likelihood the baby expired because of some interference with its circulation. Fetal asphyxia is often an accompaniment of the second stage of labor and it may prove fatal. The contraction of the cervix and the lower uterine segment could have occurred after the birth of the baby. Such contractions more often following the use of oxytocic drugs than in normal delivery. The clinical picture described is by no means rare, particularly in previable and premature deliveries.

CLINICAL USE OF THE CHAMBERLAIN TECHNIC IN SACROILIAC CONDITIONS

RANDOLPH L. ANDERSON, M.D.

AND

VERNON L. PETERSON, M.D.

CHARLESTON, W. VA.

The question of sacroiliac slip has been discussed for years. Snelling published a paper on this subject in 1870. Goldthwaite and Osgood made an important contribution in 1905. Fick, Smith-Petersen and others have also made their contributions. There seems to be no question at the present time but that the sacroiliac joint is a movable joint.

Chamberlain in 1919 first began to use his x-ray technic of demonstrating slipping of the sacroiliac joints. He read a report on this subject at a meeting of the American Roentgen Ray Society in September 1922. Allen published the description of a somewhat similar technic in 1923. Chamberlain¹ has published papers in 1930 and 1932 on this subject.

Chamberlain states that "there is no reason to expect the ordinary anteroposterior view of the sacroiliac region to reveal the normal or abnormal movement occurring in these joints because motion of the sacroiliac joint is not in a direction which could be shown by any sort of x-ray study of the joint itself. The sacroiliac motion, when it occurs, is rotatory, and the rotation takes place within an axis which is perpendicular to the joint surface. The place to look for evidence of sacroiliac joint motion is at the symphysis pubis, where it is magnified and measurable." Chamberlain makes first the ordinary routine stereoscopic posterior views which are made with the patient supine on the Potter-Buckey diaphragm table, and with the symphysis pubis and the entire pelvic rim in the field of view. Also a lateral film is taken, either right or left, centered over the lumbosacral joint.

Next the special technic is then described by him as follows: "Expose the pair of special anterior projections of the pubis, the patient standing with weight bearing on the alternate leg. In these views it is advisable to have the Potter-Buckey diaphragm mounted in the erect position. The patient is standing upon a pair of steps approximately 3 to 6 inches high facing the Potter-Buckey diaphragm. The first film is labeled "right" and the label is placed at the film margin, toward the patient's right, to indicate weight bearing on the right leg. The step is removed from under the left leg and the first exposure is made while the left

leg is hanging free. The label is then changed to "left" and is placed at the film margin toward the patient's left. The step is then placed under the left foot, and the one under the right foot is removed. The second film is exposed with weight bearing on the left leg, the right leg hanging free." We take also a third check x-ray film with the patient standing on both feet.

Chamberlain states that "a scale is applied first to one of the weight bearing films and then to the other in such a manner that the vertical line on the scale lies in the soft tissue zone, midway between the bony outlines of the two pubes. The difference in the height of the two sides of the pubes is then measured."

He states that in 90 per cent of his cases the sacroiliac symptoms have been on the side of the high pubic bone. He states that "the normal movements range from nothing to 0.5 mm. in the male and from nothing to 1.5 mm. in the nonpregnant female.

This x-ray technic has been used by one of us, V. L. P., a roentgenologist, and the senior author for the past two and one-half years in 144 cases. A careful history is taken, and the ordinary clinical tests used in low back examinations have been made in all cases. The methods of Nutter, Pitkin² and others demonstrating undue mobility of the sacroiliac joint clinically have not been made. The total of 144 cases studied were cases which seemed to be somewhat obscure so far as their diagnosis was concerned. These were consecutive cases and were not selected.

One hundred and seventeen of these patients were male and 27 were female. Sacroiliac slip occurred in 35 of the 117 cases in males, or 29.9 per cent. It occurred in 16 of the 27 cases in females, or 59.2 per cent.

Thirty-five of the 144 cases were private cases and 109 were compensation cases. Twenty-three, or 65.7 per cent, of the private cases showed a slip. Twenty-eight, or 25.7 per cent, of the compensation cases showed slipping. It is believed that this examination is especially useful in compensation cases, as it is well known that they are more difficult to evaluate than ordinary private cases.

The onset of the trouble was due to an accident in 131, or 91 per cent of the whole series of cases, and the onset was gradual in 13, or 9 per cent of the whole series. In the cases showing sacroiliac slip 43, or 84 per cent, were due to accident and 8, or 16 per cent, were gradual in their onset. Thus it seems that while accidents predominate as the cause of slipping it is by no means unusual to see slipping in cases without previous history of accident.

Low back pain was the chief complaint in all of these cases. Associated leg pain was found in 65, or 46 per cent, of the whole series and in 24, or 46 per

1. Chamberlain, W. E.: The X-Ray Examination of the Sacroiliac Joint, Delaware M. J. 4:195-201, 1932; The Symphysis Pubis in the Roentgen Examination of the Sacroiliac Joint, Am. J. Roentgenol. 24:621-625, 1930.

2. Pitkin, H. C., and Pheasant, H. C.: Sacroarthrogenetic Telalgia: I. A Study of Referred Pain, J. Bone & Joint Surg. 18:111-133 (Jan.) 1936.

cent, of the cases showing sacroiliac slip. Then in 54 per cent of the cases leg pain was absent and the pain was confined to the lower back and gluteal region.

A routine back examination was made in these cases with special reference to list, limitation of straight leg raising, limitation of spine motions, Trendelenburg, Gaenslen, Ober and Ely signs, compression and separation of the pelvis, and points of maximum tenderness. The question of posture and limp were all considered.

Fig. 1 (patient T.).—Appearance with patient standing on both feet.

Fig. 2 (patient T.).—Patient standing on the left foot: no displacement in the left sacroiliac joint.

Fig. 3 (patient T.).—Patient standing on right foot: displacement of 2.5 mm.

It is interesting to note that a list was found in comparatively few of these cases.

On the other hand, straight leg raising was found to be limited in 59 per cent of the whole series of 144 cases and was found in 93 per cent of the 51 cases showing sacroiliac slip. Thus it can be said that a normal straight leg raising test will almost eliminate a sacroiliac slip.

As was to be expected, there was considerable limitation of spine motion, that is as regards motion in the lumbar spine, in many cases. This point was of little use in differentiating sacroiliac lesions from other conditions, however.

The Trendelenburg test was positive in comparatively few cases and was found to be of little help.

The Gaenslen test was found to be positive in a little over one fifth of the whole series of 144 cases and also

percentage of the cases. It did not seem to be of definite help in making the diagnosis of this condition.

As was to be expected, the sacroiliac joint was the usual point of maximum tenderness. It was present in 76, or 52 per cent, of the whole series of 144 cases and in 30, or 58.8 per cent, of the cases showing sacroiliac slip. Sciatic tenderness was present in less than 1 per cent of the whole series but in 4 cases, or 7 per cent, of the cases showing sacroiliac slip.

All patients showing definite sciatic symptoms were referred to a neurologic surgeon for further neurologic studies and studies with iodized oil if indicated.

Poor posture was found in a comparatively small percentage of these cases showing sacroiliac slip, 3 cases, or 5.8 per cent. A limp was found in only 5 cases, or 10 per cent, of the cases showing sacroiliac slip.

The x-ray examination showed sclerosis in 35, or 24 per cent, of the whole series of 144 cases and this was present in only 8 cases, or 15 per cent, of the cases showing sacroiliac slip.

It has been found by Pitkin and others that sacroiliac slips are present more commonly on the left side than on the right. In our series 15 cases, or 29.4 per cent, showed slipping on the right side and 27 cases, or 52.9 per cent, showed slipping on the left. Nine

Fig. 4 (patient B.).—Appearance with patient standing on both feet.

Fig. 5 (patient B.).—Patient standing on left foot with displacement of 1.5 mm.

Fig. 6 (patient B.).—Patient standing on right foot, displacement of 3 mm.

in about the same percentage in the cases showing a sacroiliac slip.

The Ober test was found to be positive in a somewhat higher percentage of the cases. It was positive in 40 per cent of the whole series of 144 cases and in 35 per cent of the cases showing sacroiliac slip.

The Ely test was found to be positive in about one third of the whole series and in only about 25 per cent of the cases showing a sacroiliac slip.

Pain on attempted separation or compression of the pelvis was found to be present in a comparatively small

cases, or 17.6 per cent, had a bilateral slipping by x-ray examination.

Twenty-nine cases, or 20 per cent of the whole series, showed positive sacroiliac signs and the x-ray examination showed a slipping on the same side. Eight cases, or 5.5 per cent of the whole series, showed positive sacroiliac signs on both sides and the x-ray examination showed slipping on both sides. Seventy-one cases, or 49 per cent of the whole series, showed sacroiliac signs which were predominantly negative on both sides and the x-ray examinations were negative on both sides.

Two cases, or 1.3 per cent of the whole series, showed positive sacroiliac signs on both sides and the x-ray examination showed a slipping on one side only. One case, or 0.67 per cent of the whole series, showed positive sacroiliac signs on one side and x-ray examination showed slipping on both sides.

On the other hand, 8 cases, or 5.5 per cent of the whole series, showed sacroiliac signs which were inconclusive and the x-ray examination showed a slipping on the same side. In 6 cases, or 4.16 per cent of the whole series, the sacroiliac signs were inconclusive and the x-ray examination showed a slipping on the opposite side. Also 14 cases, or 9.7 per cent of the whole series, showed sacroiliac signs which were positive on one side and the x-ray examination was negative. Five cases, or 3.4 per cent of the whole series, showed sacroiliac signs which were positive on both sides and x-ray examination were negative bilaterally.

Now, to recapitulate, the sacroiliac signs and x-ray findings agreed completely in 108 cases, or 74.5 per cent of the whole series. The sacroiliac signs and x-ray findings agreed partially in 11 cases, or 7.6 per cent. Thus, in a total of 82.1 per cent the x-ray examination showed agreement with the essential clinical findings. On the other hand, the sacroiliac signs and the x-ray findings were in disagreement in 25 cases, or 17.9 per cent.

The x-ray films were available for review in 42 of the 51 cases showing sacro-iliac slip. Of these cases the right sacroiliac joint was involved in 16 males and 10 females. There was an average of 1.9 mm. of slipping in the male, disregarding the slip in 1 case which was 10 mm. There was an average slipping of 1.8 mm. in the female.

The left sacroiliac joint showed 16 males involved with an average slipping of 1.47 mm., and 11 females with an average slipping of 1.68 mm.

Of the 42 cases involving 53 joints in which x-ray measurements were made, 37 of these cases and 46 joints showed slipping above the normal of 0.5 mm. in the male and of 1.5 or more millimeters in the female. Thirty of these joints were in the male and 16 in the female.

An analysis of these 37 cases is of interest. Twenty-one out of these 37 cases, or 56 per cent, were cases in which the sacroiliac signs were positive and the x-ray examinations showed slipping on the same side. In 5 of these cases, or 13.5 per cent, the sacroiliac signs were positive on both sides and the x-ray examinations showed a slipping on both sides. In a total of 26 out of 37 cases, or 70 per cent, there was complete agreement between the x-ray and the clinical findings. In 2 cases, or 5.4 per cent, the sacroiliac signs were positive on both sides and x-ray examinations showed slipping on one side only. In 2 cases sacroiliac signs were positive on one side and the x-ray examinations showed slipping on both sides. In 5 cases, or 13.5 per cent, the sacroiliac signs were inconclusive and the x-ray examinations showed slipping on the same side. In 2 cases the sacroiliac signs were inconclusive and the x-ray examinations showed slipping on the opposite side.

CONCLUSION

The so-called Chamberlain technic of x-ray examination of the sacroiliac joint is worth while and is accurate in 70 to 80 per cent of the cases. It should be used in doubtful cases of sacroiliac joint conditions.

FETAL AND NEONATAL MORTALITY IN PREGNANCIES COMPLICATED BY DIABETES MELLITUS

HERBERT C. MILLER, M.D.

NEW HAVEN, CONN. -

DAVID HURWITZ, M.D.

BOSTON

AND

KATHERINE KUDER, M.D.

NEW YORK

About 30 per cent of all the pregnancies complicated by diabetes mellitus result in the death of the fetus or the newborn infant. The cause of this high mortality has remained obscure. No significant reduction in fetal deaths has been shown to have occurred since insulin has come into use. Several factors have been held responsible for the high death rate. These include the degree of care with which the maternal diabetes has been regulated, the presence of such complications of pregnancy as toxemia and hydramnios, the frequent occurrence of large fetuses, the increased incidence of congenital anomalies and the hypoglycemia in the live-born infant. There is no general agreement, however, that any one or that all of these factors together can explain satisfactorily the fetal mortality.¹

A recent study by Miller and Wilson² has brought out the fact that infants born of diabetic mothers may have cardiac hypertrophy and excessive erythropoiesis in the liver with large numbers of nucleated red blood cells in the peripheral blood during the first days of life. The cardiac and hepatic changes were found by them associated sometimes with hyperplasia of the islands of Langerhans in overweight fetuses. The anatomic changes described were noted to have been present in 2 instances before maternal diabetes was manifest. The frequent occurrence of this syndrome in infants born to diabetic mothers suggested that there might be some causal relationship between it and diabetes mellitus. The fact that it was sometimes present before the onset of recognizable signs and symptoms of diabetes indicated that the anatomic changes were not related to

the hyperglycemia in the mother. These observations were based on autopsies done on infants at the Boston Lying-in Hospital, the New Haven Hospital and the New York Hospital. The anatomic changes reported by Miller and Wilson were the result of a preliminary survey. A more detailed study of the postmortem material from the three hospitals is to be made in the near future under the direction of Dr. Arthur T. Hertig of the Boston Lying-in Hospital. It was felt that while the autopsy material was being studied a survey of all the pregnancies complicated by diabetes in the three hospitals should be made. The purpose of the investigation was to evaluate all the factors which might have a bearing on the survival of the fetus. Studies of this kind have been made before, but seldom has there been an opportunity to report enough cases to give statistical significance to the results.

The 123 mothers had 143 pregnancies and there were 146 births, the results of which are shown in table 1. The fetal and neonatal mortality in the diabetic pregnancies have been compared to those in 3,079 consecutive births which occurred in the New Haven Hospital from 1928 to 1932 inclusively.⁴ The total mortality among the 3,079 births was 5.4 per cent. The mortality among the 146 births to diabetic mothers was 29.4 per cent, or about five times higher than in the non-diabetic group. The fetal mortality was six times and the neonatal mortality was four times higher in the diabetic group than in the non-diabetic. Twenty-two of the 30 fetal deaths were macerated fetuses. The high death rate among the fetuses and liveborn infants of diabetic mothers is not related primarily to the severity of the maternal diabetes. In the group of 123 diabetic mothers there were 42 who were classified as having diabetes but who did not require insulin at

TABLE 1.—Fetal and Neonatal Deaths in Diabetic and Nondiabetic Pregnancies, Showing Effect of Mild Diabetes and Uncomplicated Pregnancies on the Fetal and Neonatal Mortality.

Group	Births	Fetal Deaths *		Neonatal Deaths *		Total Deaths		Chi Square

The chi squares in the column marked "Total" represent the significance of the difference between the mortality in the five year period immediately preceding the onset of diabetes and the mortality in each of the other five year periods in the prediabetic era. The chi squares in the column marked "Nondiabetic" refer to the significance of the difference between the mortality in nondiabetic and total diabetic in the corresponding five year periods.

MATERIAL

The material for this study was obtained from the hospital records of all diabetic pregnant women and their offspring admitted to the Boston Lying-in Hospital, the New Haven Hospital and the New York Hospital since 1930, 1928 and 1933 respectively.³ No diabetic mother was accepted for study who was admitted to a hospital for the delivery of a fetus that weighed less than 1,000 Gm. On this account 5 mothers and their fetuses were excluded. There remained 137 mothers who were observed in the three hospitals through 159 pregnancies. There were 162 births. The statistical significance of the results was determined by the chi square test. A chi square of 3.8 or more may be considered as statistically significant.

RESULTS

In the group of 137 mothers there were 123 whose diabetes had its onset either before or during the pregnancy for which they were admitted to the hospital.

any time during pregnancy. The diagnosis of diabetes was made in these 42 mothers on the fact that they had glycosuria with or without symptoms plus the fact that in all but 2 instances either the dextrose tolerance curve was of the diabetic type or the fasting blood sugar was over 140 mg. per hundred cubic centimeters. There were 48 births in 45 pregnancies among the 42 mothers, and the mortality for the infants is shown in group 3, table 1. The combined fetal and neonatal mortality was 22.9 per cent, or four times higher than the mortality in the nondiabetic group. This high death rate among the offspring of the diabetic mothers who did not require insulin is not the result of maternal complications of pregnancy, for the mortality is almost the same even when the maternal complications are excluded as a possible cause (see Group 3a table 1). Under the most favorable conditions the risk to the infant of a diabetic mother is about four times that to the infant born to a nondiabetic woman. In the presence of severe complications of pregnancy in women

4. Hadley, E. E.: Morbidity and Mortality in the Neonatal Period, Thesis, Yale University, 1934.

3. Footnote deleted on proof.

with diabetes, the risk to the infant may be greatly increased. The mortality among the infants whose mothers had severe complications of pregnancy with both mild and severe diabetes was 43.6 per cent (group 2a, table 1). A clear understanding of the cause of the high mortality in diabetic pregnancies will not be had, however, until the explanation for the high mortality in the noncomplicated group is obtained.

There is ample evidence that the fetal and neonatal mortality is extraordinarily high long before the mothers develop symptoms or signs of diabetes. In table 2 there has been presented the results of all the pregnancies exclusive of abortions and miscarriages that occurred in those mothers who had pregnancies both before and after the onset of diabetes. The diabetic mothers in table 2 have been divided into two groups: those whose diabetes required insulin during pregnancy and those whose diabetes was regulated solely by diet. The appearance of the first sign or symptom as recorded in the history was taken as the onset of diabetes in both groups of women. The births and deaths in the two groups have been given not only for the period when diabetes was present but also for the years before the onset of diabetes. The latter period has been arbitrarily divided into periods of five years each. The births and deaths that occurred in a group of 106 nondiabetic mothers whose average age at the time of the birth of their last infant was the same as that of the diabetic women at the time of onset of their diabetes, 34 years, are also given in table 2. The nondiabetic women were unselected consecutive patients admitted to the New Haven Hospital for delivery in 1943. In both the insulin and non-insulin treated diabetic groups the fetal and neonatal mortality follows the same pattern. The number of deaths increases as the onset of diabetes is approached, and in the five year period immediately preceding the appearance of signs and symptoms of the diabetic syndrome the mortality is higher than in any other preceding period. The statistical significance of the increase in mortality as diabetes approaches is demonstrated by combining the data in the insulin treated and non-insulin treated groups and comparing the mortality in the five year period immediately preceding the onset of symptoms with each five year period before it. Furthermore, the mortality for the diabetic group in each one of the five year periods before the onset of diabetes is statistically significantly higher than the mortality in the corresponding five year period in the nondiabetic group. In the five year period immediately preceding the onset of diabetes the mortality is higher than that after diabetes is recognized, but the difference is not statistically a significant one.

It is well known that babies born to diabetic mothers tend to be overweight. This increased birth weight can be shown to antedate in the offspring the appearance of diabetic symptoms and signs in the mother. In table 3 the incidence of babies who weighed over 5 Kg. at birth is given.⁵ In the babies born to mothers before the latter became diabetic a history of a birth weight of 5 Kg. or more was accepted only if the baby had been born in a hospital where accurate weights could be obtained, since histories of home weights are grossly unreliable. The incidence of babies who weighed more than 5 Kg. at birth was 3.9 per cent before diabetes

was diagnosed in the mothers and 6.4 per cent after the onset. Statistically, both of these figures are significantly higher than the incidence of similar babies in the nondiabetic population. The earliest recorded birth weight in excess of 5 Kg. among 256 births was ten years before the appearance of diabetic symptoms.

The excessive size of the fetus has been held by some investigators to be responsible for part of the high mortality in infants born to diabetic mothers. The relation between the birth weight and mortality was studied in this series, and the results are given in table 4. There is nothing in the data of table 4 to indicate that an excessive birth weight decreases the infant's chances for survival. It might be supposed that maceration might influence the birth weights adversely in the lower weight brackets, but even with macerated fetuses eliminated the mortality is no more unfavorable for the infants over 4.5 Kg. than those in the normal range. There were 6 infants with birth weights over 5 Kg. and 2 deaths, indicating possibly that in this very high weight range the mortality does

begin to increase. The mortality is very high in infants under 2.5 Kg., as would be expected in premature infants.

Among the 137 mothers whose records were studied there were 11 who had glycosuria but who could not be considered as having diabetes, as they had either normal fasting blood sugar concentrations or normal dextrose tolerance curves during pregnancy. In 2 instances, cases 6 and 8 of table 5, no tests were done, so that they could not be classified for certain as diabetic and hence were included in this group. In only 1 instance, case 1, did diabetes subsequently develop in a mother. The group of cases in table 5 have been shown because the number of fetal and neonatal deaths, the incidence of large fetuses and the occurrence of cardiac hypertrophy and erythropoiesis in the liver and blood seemed similar to the results observed in the larger group of births among the definitely diabetic mothers shown in the previous tables. There were 4 deaths, in cases 1, 2a, 2b and 3, among the 12 births listed in table 5, or a mortality of 33 per cent. Three of the infants weighed over 5 Kg. at birth, in cases 2b, 3 and 4. In 2 infants an enlarged heart was noted on roentgen examination, cases 1 and 4.

5. The figures for the nondiabetic at the Chicago Lying-in Hospital were obtained from Koff, A. K., and Potter, Edith L., Complications Associated with Excessive Development of Human Fetus, *Am. J. Obst. & Gynec.* 38: 412 (Sept.) 1939.

In the same 2 cases large numbers of erythroblasts were observed in the peripheral blood and in another infant, case 3, there were numerous areas of erythropoiesis in the liver at autopsy.

COMMENT

The belief has long been held that the hyperglycemia in the pregnant diabetic woman is responsible for the large number of fetal and neonatal deaths, the excessive birth weight of some of the infants and the hyperplasia of the islands of Langerhans in the fetal pancreas. This opinion is no longer tenable in the light of the evidence presented here. Fetal and neonatal deaths and the birth of unusually large babies occur with about the same incidence before diabetes becomes manifest as afterward. Hyperplasia of the islands of Langerhans, cardiac hypertrophy and excessive erythropoiesis in the fetal liver, which are found in the newborn of diabetic women, have also been demonstrated to occur in infants before symptoms or signs of diabetes could be recognized in their mothers. There is no reason for assuming that the factor or

found in infants weighing considerably less. Furthermore, there were some women who, although they had several pregnancies before and after the onset of their diabetes, had none that resulted in the death of the fetus or newborn infant. Just why some fetuses escape and why the lethal factor does not repeat itself from one pregnancy to another require an explanation as much as the large number of fetal deaths. Two facts are clear from the present study. The lethal factor for the fetus may be in effect from fifteen to twenty years before the onset of diabetes can be recognized, and the effect of the lethal factor becomes greater as the mother approaches the onset of clinical signs and symptoms of the syndrome. Many other facts will be needed, however, before the relationship between fetal death, overweight fetuses and the eventual production of hyperglycemia in the mother is clarified. White and Hunt have stated that fetal death in the diabetic woman is associated with a high concentration of gonadotropic substance in the maternal serum during the latter part of pregnancy and that the administration of estrogens and progesterone can prevent the large number of

factors that cause fetal and neonatal deaths and that lead to the production of unusually large infants and the other anatomic changes in the viscera of the fetus during the years before diabetes can be diagnosed are not identical with those that are producing the same results after the syndrome has become established.

The birth of large babies and the frequent occurrence of fetal deaths before the appearance of diabetic symptoms has also been noted by Allen.⁶ According to him "glycosuria is only another manifestation of a condition that may produce larger babies and sometimes kill them before birth." This is a vague statement and is far from being proved, since the nature of the "condition" remains obscure. There is no certainty even that the lethal factor for the fetus is identical either with the one that produces large fetuses or with the one that leads to the visceral changes in the fetus. In the present study no correlation could be found between the birth weight of the infant and the mortality. The number of deaths was no higher in babies that weighed over 4.5 Kg. than in those that weighed from 2.5 to 3.5 and from 3.5 to 4.5 Kg. Although the visceral changes described by Miller and Wilson apparently tend to occur more frequently in fetuses that weigh more than 4 Kg., the changes were also

fatalities.⁷ This contention is not borne out by the investigations of the Smiths, who noted fetal and neonatal deaths in the presence of normal serum levels of gonadotropic substance in the diabetic mothers' bloods⁸ and observed normal infants to be born in spite of decidedly elevated concentrations of gonadotropic substance in other mothers with diabetes.⁹ Whether or not the administration of estrogens and progesterone to the mother during the latter months of pregnancy will prove effective in lowering fetal mortality must await further trial, since White's series of cases is too small to permit any definite conclusions. For obvious reasons the anterior pituitary has been considered by some as playing an important part in the production of large fetuses and the high incidence of fetal and neonatal deaths. Although the role of the anterior pituitary in the production of diabetes has recently received great emphasis, considerably more work must be done before the death of the human fetus and newborn infant and the excessive size

6. Allen, E.: Glycosurias of Pregnancy, Am. J. Obst. & Gynec. **38**: 982, 1939.

of the infant can be ascribed to this gland. It is true that the injection of extracts of the anterior pituitary lead to the production of postmature fetuses and a high fetal mortality in animals,¹⁰ but there is no work as yet to suggest that the infants of diabetic mothers have an abnormally prolonged gestation period.

A large percentage of patients in the present study included women who could be classified as mildly diabetic. They had glycosuria, diabetic dextrose tolerance curves and high fasting blood sugars but did not require insulin. There has been a tendency in some clinics to minimize the importance of this group. The evidence presented here indicates that with respect to fetal mortality and the production of somatic and visceral changes in the fetus they are to be considered similar to the infants of women whose diabetes is severe and of long standing.

A special group of 11 mothers were observed who had glycosuria but who could not be diagnosed as diabetic, since the carbohydrate metabolism was otherwise within normal limits. The fact that the offspring of these women showed the same changes and the same poor chances for survival as did those born to mothers with outspoken diabetes indicates that glycosuria in the latter months of pregnancy is not to be regarded as "benign" for the fetus. The importance of even a single observation of dextrose in the urine is revealed in case 4 of table 5. During this particular pregnancy the mother had tests for sugar done on her urine on twenty different occasions, and reducing substances were found only once. The large number of tests were done because she had glycosuria for seven months prior to a previous pregnancy. The twenty tests reveal how completely the glycosuria had subsequently disappeared. In spite of the fact that the evidence of diabetes is practically nil during this pregnancy, the infant was found to weigh 5.4 Kg. at birth, had on roentgen examination an enlarged heart and was found to have 71 erythroblasts per hundred white blood cells in the peripheral blood—a clinical picture that is encountered with considerable frequency in babies of diabetic mothers. The fact that fetal death and pronounced somatic and visceral changes can occur in infants born to women with so little evidence of diabetes, and for many years before diabetes can be considered on any grounds, suggests that there may be occasions when fetal deaths occur and large babies are born and yet the mother may never develop the recognizable signs and symptoms of diabetes. The solution of the cause of fetal death and large babies in pregnant diabetic women may give us more light not only on diabetes but also on the causes of unexplained fetal death.

CONCLUSIONS

1. In pregnancies complicated by diabetes mellitus the fetal and neonatal mortality is about five times higher than that in nondiabetic pregnancies. The fetal and neonatal mortality is as high during the five years immediately preceding the onset of diabetic symptoms as after the syndrome has become established. An increased fetal and neonatal mortality can be observed from fifteen to twenty years before the clinical symptoms and signs of diabetes can be recognized.

2. Infants with a birth weight of 5 Kg. or more are born to women before they become diabetic with

the same high frequency as after diabetic symptoms have appeared. The incidence of infants whose birth weight is 5 Kg. or more is about eighty times higher in pregnancies complicated by diabetes than in non-diabetic pregnancies.

3. The fetal and neonatal mortality is no higher among those infants who weigh 4.5 Kg. or more at birth than among those who weigh between 2.5 and 4.5 Kg.

4. In the presence of mild diabetes (not requiring insulin) and in the absence of maternal complications of pregnancy the fetal and neonatal mortality is four times higher than that in the nondiabetic population. Severe complications of pregnancy in women with diabetes increase the risk to the infant.

5. The presence of glycosuria in the last months of pregnancy in women whose carbohydrate metabolism is otherwise apparently normal is associated with a fetal and neonatal mortality that is as high as that among the offspring of women with definite diabetic signs and symptoms.

CLINICAL ASPECTS OF SHOCK

JOHN McMICHAEL, M.D.(EDIN.), F.R.C.P.E.,
M.R.C.P.(LOND.)

Reader in Medicine and Acting Director, Department of Medicine,
British Postgraduate Medical School
LONDON, ENGLAND

The difficulties which beset the study of shock in wartime are obvious. Casualties, when they occur, are apt to be in overwhelming numbers, and the available clinical staff to deal with the cases is so overworked with urgent therapeutic procedures that adequate recording and study may be impossible. For this reason clinical data on shock are infinitely more scanty than reports on animal experimentation. In this school and hospital some 200 wounded patients were admitted during the London air raid period; of these, 28 had injuries of such severity as to require blood transfusion. In spite of considerable reduction of staff, circumstances were thus reasonably favorable for simple clinical observations and records to be made. It is on the basis of this experience that the opinions expressed in this paper are put forward.

When the present conflict began, views generally held of the nature of traumatic shock were those which had been reached at the end of the last war, with certain important modifications of outlook established by such experimental investigators as Blalock.¹ A fundamental feature of wound shock was taken to be a depleted circulating blood volume (oligemia). The investigators of the last war had made something of a mystery of the loss of blood, but since then the experimentalists had realized that probably the major part was lost by hemorrhage and exudation into the injured tissues.

CLASSIFICATION

Any attempt to produce a complete clinical classification of shock can be only provisional, as it is not yet possible to include all the complex factors involved. Blalock's classification into hematogenic, cardiogenic,

CASE 2 (by permission of the director of medical service, Royal Canadian Army Medical Corps).—A soldier during exercises was accidentally thrown from his motorcycle under a tank. Treatment in the hospital was begun within one hour. His injuries consisted of a compound fracture of the humerus, fractures of the ninth, tenth and eleventh ribs and also of the second, third and fourth lumbar transverse processes, a ruptured right kidney, a simple fracture of the right ankle, together with concussion and scalp lacerations. His blood pressure remained unrecordable until 2 liters of plasma and blood had been given: 3.5 liters brought his blood pressure to 100 mm. of mercury at the end of two hours. At the end of four hours, when 5.5 liters of blood and plasma had been given, he was fit for operation. His wounds were excised, the fractures were reduced and the abdomen was opened to make sure of the absence of intraperitoneal hemorrhage. A large retroperitoneal hematoma was present, which was left alone. During the operation a further liter of blood was given. The patient made an excellent recovery and was up in the ward in ten days.

It is unnecessary to seek any cause for the collapse in these cases other than the hemorrhage, which is quantitatively adequate to account for the clinical state, quantitative replacement in each case being followed by a satisfactory outcome.

Circulatory Collapse Due to Plasma Loss.—As I have already stated, circulatory collapse due to plasma loss is a rare occurrence except in burns and crushing injuries. As a result of tissue trauma in these cases the "permeability" of the capillaries is altered and a fluid closely resembling plasma leaks out into the tissues. In some of our cases of crushing injury the hemoglobin rose as high as 140 to 160 per cent. The shock which resulted is not of a special type, since the fall in blood pressure was fully accounted for by fluid loss. The blood pressure was invariably restored to normal by redilution of the blood to a more normal hemoglobin level by plasma or serum transfusions. The fall in blood pressure in these cases, however, was very profound.

Although the circulatory effects of crushing injuries are relatively simple in their essential features, the more important sequela of this type of trauma is renal failure. This syndrome, which is now usually called the "crush syndrome," has been fully described elsewhere.¹² Various products from necrotic muscle (myohemoglobin, potassium phosphate and other substances) leak out into the circulation when this is reestablished locally following release from the compressing injury, and severe renal impairment with death in uremia follows in 66 per cent of the cases.

II. HEMODYNAMIC SEQUELAE OF OLIGEMIA
